AN INVOLUTIVE INTRODUCTION TO SYMMETRIC FUNCTIONS

MARK WILDON

PREFACE

In Autumn 2015 I gave a 10 lecture course on symmetric functions at Royal Holloway, University of London, following a slightly unconventional path that emphasised bijective and involutive proofs. This is an expanded version of the lecture notes. Subsections marked * are not logically essential. A recurring theme is the combinatorial and algebraic meaning of the transition matrices between the various bases of the ring of symmetric functions. For example:

Outline. In §1 the families of elementary, complete homogeneous and power sum symmetric functions are defined. Schur functions are defined combinatorially, using semistandard tableaux, and shown to be symmetric by the Bender–Knuth involution. Motivation comes from combinatorial results including the Gale–Ryser Theorem, MacMahon’s Master Theorem, and the Cycle Index Formula for the symmetric group. The ring of symmetric functions is defined formally and then shown to be an inverse limit of the graded rings of symmetric polynomials.

In §2 the Jacobi–Trudi Identity is proved ‘by sufficiently general example’ using a special case of an involution due to Lindström and Gessel–Viennot. This is now a standard proof: it may be found in [14, §7.16] or [13, §4.5].

In §3 we switch focus to antisymmetric polynomials, and present the elegant involutive proofs in [8] of the Pieri, Young and Murnaghan–Nakayama Rules using Loehr’s abacus model. A textbook account may be found in [9]. These are results on the Schur polynomials, defined as a quotient of two antisymmetric determinants, so do not obviously relate to the Schur functions already defined. In §4 we establish the equivalence of the two definitions using the Lascoux–Schützenberger involution (originally defined in [7]).

In §5 we unify the results so far using the Hall inner product and the ω involution on the ring of symmetric functions. We then prove the key properties of the characteristic isometry, relating class functions of symmetric groups and symmetric polynomials and apply it to prove Pólya’s Cycle Index Formula.

Date: July 2017.
The Jacobi–Trudi formula and the Lascoux–Schützenberger involution extend to Schur functions labelled by skew partitions. This generality adds considerably to their utility, but appeared excessive in the early lectures. It was assumed in the final lecture, where I used the Lascoux–Schützenberger involution to give a proof of the Littlewood–Richardson Rule. The proof is given as a series of questions in §6, starting with Question 26. Most of these questions are on well-known results or proofs: possible exceptions are Question 7 (generalized derangements), Question 13 (an easy way to go wrong in the proof of the Jacobi–Trudi Identity) and Question 21 (an involutive proof of the Murnaghan–Nakayama Rule). Hints, references or solutions for all the questions are given in the final section.

Comments. Comments are very welcome. In particular I gratefully acknowledge extremely detailed comments and corrections from Darij Grinberg on an earlier version of these notes. I also thank Eoghan McDowell for helpful comments and corrections. Of course I have full responsibility for the remaining errors.

1. INTRODUCTION: DEFINITIONS AND MOTIVATION

1.1. Preliminary definitions. The following definitions are standard. Note in particular that partitions have infinitely many parts, all but finitely many of which are zero. Permutations act on the right.

Compositions and partitions. A composition of \( n \in \mathbb{N}_0 \) is an infinite sequence \( (\alpha_1, \alpha_2, \ldots) \) such that \( \alpha_i \in \mathbb{N}_0 \) for all \( i \) and \( \alpha_1 + \alpha_2 + \cdots = n \). (The term 'weak composition' is also used in the literature.) The sequence elements are called parts. By this definition, there is a unique composition of 0, which we denote \( \emptyset \). If \( \alpha \neq \emptyset \), let \( \ell(\alpha) \) be the maximum \( r \) such that \( \alpha_r \neq 0 \) and let \( \ell(\emptyset) = 0 \). If \( \ell(\alpha) \leq N \) then we write \( \alpha = (\alpha_1, \ldots, \alpha_N) \). A composition \( \alpha \) is a partition of \( n \) if \( \alpha_1 \geq \alpha_2 \geq \cdots \) and \( \alpha_1 + \alpha_2 + \cdots = n \). We write \( \alpha \vdash n \) to indicate that \( \alpha \) is a composition of \( n \) and \( \lambda \vdash n \) to indicate that \( \lambda \) is a partition of \( n \).

It is often convenient to use exponents to indicate multiplicities of parts: thus \((m^{a_m}, \ldots, 2^{a_2}, 1^{a_1})\) denotes the partition with exactly \( a_j \) parts equal to \( j \), for each \( j \in \{1, \ldots, m\} \). For example,

\[
(4, 4, 2, 1, 1, 1, 0, \ldots) = (4, 4, 2, 1, 1, 1) = (4^2, 3^0, 2^1, 1^3).
\]

The Young diagram \([\lambda]\) of a partition \( \lambda \) is the set \( \{(i, j) : i, j \in \mathbb{N}, 1 \leq i \leq \ell(\lambda), 1 \leq j \leq \lambda_i\} \). We represent Young diagrams by diagrams, such as the one shown below for \((4, 2, 1, 1)\):

\[
\begin{array}{ccc}
\square & \square & \square \\
\square & \square \\
\end{array}
\]

The conjugate of a partition \( \lambda \) is the partition \( \lambda' \) defined by

\[
\lambda'_j = |\{i : \lambda_i \geq j\}|.
\]
By definition $\lambda' = r$ if and only if $\lambda$ has exactly $r$ parts of size $j$ or more, or equivalently, if and only if column $j$ of $[\lambda]$ has length $r$. Thus $[\lambda']$ is obtained from $[\lambda]$ by reflection in the main diagonal. In particular $\lambda'' = \lambda$ for any partition $\lambda$.

Orders on partitions. The dominance order on partitions of $n$, denoted $\geq$, is defined by $\lambda \geq \mu$ if and only if $\lambda_1 + \cdots + \lambda_c \geq \mu_1 + \cdots + \mu_c$ for all $c \in \mathbb{N}$. It is a partial order: for example $(3, 1, 1, 1)$ and $(2, 2, 2)$ are incomparable. It is usually the right order to use when working with symmetric functions or symmetric groups. The lexicographic order, denoted $>$, is defined by $\lambda > \mu$ if and only if $\lambda_1 = \mu_1, \ldots, \lambda_{c-1} = \mu_{c-1}$ and $\lambda_c > \mu_c$ for some $c$. It is a total order refining the dominance order. (The word ‘refining’ is mathematically correct, but may give the wrong impression: more precise information comes from using the dominance order.)

Symmetric group. Let $\text{Sym}(X)$ denote the symmetric group on a set $X$. Let $\text{Sym}_n = \text{Sym} \{1, \ldots, n\}$. In these notes permutations act on the right. For example, the composition of the cycles $(12)$ and $(123)$ in the symmetric group $\text{Sym}_3$ is $(12)(123) = (13)$, and the image of $1$ under the permutation $(12)$ is $1(12) = 2$.

1.2. Gale–Ryser Theorem. We begin with a combinatorial result. An $a \times b$ matrix $X$ with entries in $\mathbb{C}$ has row sums $(\sum_{j=1}^b X_{ij})_{i \in \{1, \ldots, a\}}$ and column sums $(\sum_{i=1}^a X_{ij})_{j \in \{1, \ldots, b\}}$. A matrix is 0-1 if all its entries are either 0 or 1.

**Theorem 1.1** (Gale–Ryser). Let $\lambda$ and $\mu$ be partitions of $n$. There is a 0-1 matrix $X$ with row sums $\lambda$ and column sums $\mu$ if and only if $\lambda' \geq \mu'$.

For example, take $\lambda = (4, 1, 1)$, so $\lambda' = (3, 1, 1, 1)$. If $\mu = (2, 2, 1, 1)$ then a suitable 0-1 matrix is

$$
\begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0
\end{pmatrix}
$$

while if $\mu = (2, 2, 2)$ then no such matrix exists.

By Question 2, we have $\lambda' \geq \mu$ if and only if $\lambda \leq \mu'$. The condition in the Gale–Ryser Theorem is therefore symmetric with respect to $\lambda$ and $\mu$, as expected.

*Proof that the Gale–Ryser condition is necessary.* Let $a = \ell(\lambda)$ and let $b = \ell(\mu)$. Suppose that $X$ is an $a \times b$ matrix with row sums $\lambda$ and column sums $\mu$. Think of $(\lambda_1, \ldots, \lambda_a)$ as the sizes of $a$ vehicles, and $(\mu_1, \ldots, \mu_b)$ as the sizes of $b$ families. Imagine putting someone from family $j$ into
vehicle $i$ if and only if $X_{ij} = 1$. We then have a way to dispatch the families so that no members of the same family share a vehicle. Consider the $\mu_1 + \cdots + \mu_k$ people in the first $k$ families. They occupy at most $k$ seats in each vehicle, so, looking at the first $k$ columns of the Young diagram of $[\lambda]$, we see that $\lambda'_1 + \cdots + \lambda'_k \geq \mu_1 + \cdots + \mu_k$, as required.

We will shortly use this result to relate elementary symmetric functions and monomial symmetric functions. We later use symmetric functions to prove that the Gale–Ryser condition is sufficient: see Lemma 5.4. Constructive proofs also exist: see Question 11.

1.3. The ring of symmetric functions $\Lambda$. Given a composition $\alpha$ of $n$, define the monomial $x^\alpha = x_1^{\alpha_1}x_2^{\alpha_2} \cdots$. This should be regarded purely formally for the moment. For each $n \in \mathbb{N}_0$ define $\hat{\mathcal{C}}[x_1, x_2, \ldots]_n$ to be the $\mathcal{C}$-vector space of all formal infinite $\mathcal{C}$-linear combinations of the $x^\alpha$, for $\alpha$ a composition of $n$. In symbols

$$\hat{\mathcal{C}}[x_1, x_2, \ldots]_n = \{ \sum_{\alpha} c_\alpha x^\alpha : c_\alpha \in \mathcal{C} \}.$$

Note that $x^\emptyset = 1$, so $\hat{\mathcal{C}}[x_1, x_2, \ldots]_0 = \mathcal{C}$. Let

$$\hat{\mathcal{C}}[x_1, x_2, \ldots] = \bigoplus_{n=0}^{\infty} \hat{\mathcal{C}}[x_1, x_2, \ldots]_n.$$

Then $\hat{\mathcal{C}}[x_1, x_2, \ldots]$ is a ring, graded by degree, with product defined by formal bilinear extension of $x^\alpha x^\beta = x^{\alpha+\beta}$, where $\alpha + \beta$ is the composition defined by $(\alpha + \beta)_i = \alpha_i + \beta_i$ for each $i \in \mathbb{N}$. (The hat is included to distinguish $\hat{\mathcal{C}}[x_1, x_2, \ldots]$ from the polynomial ring in the variables $x_1, x_2, \ldots$, which it properly contains. See §1.7 below.)

The symmetric group $\text{Sym}(\mathbb{N})$ acts as a group of linear transformations of $\hat{\mathcal{C}}[x_1, x_2, \ldots]$ by linear extension of $x_i \sigma = x_{i\sigma}$. We define

$$\Lambda = \hat{\mathcal{C}}[x_1, x_2, \ldots]^{\text{Sym}(\mathbb{N})}$$

to be the set of fixed points. Thus $f \in \Lambda$ if and only if $f \sigma = f$ for all $\sigma \in \text{Sym}(\mathbb{N})$. If $f, g \in \hat{\mathcal{C}}[x_1, x_2, \ldots]$ then $(fg) \sigma = (f \sigma)(g \sigma)$. Thus $\Lambda$ is a subring of $\hat{\mathcal{C}}[x_1, x_2, \ldots]$, again graded by degree. Set $\Lambda_n = \Lambda \cap \hat{\mathcal{C}}[x_1, x_2, \ldots]_n$. The elements of $\Lambda_n$ are called symmetric functions of degree $n$. For example, a basis for $\Lambda_3$ is

$$x_1^3 + x_2^3 + \cdots,$$
$$x_1^2 x_2 + x_1 x_2^2 + x_1^2 x_3 + \cdots,$$
$$x_1 x_2 x_3 + x_1 x_2 x_4 + \cdots.$$

Remark 5.9 gives one reason why it is necessary to work with infinitely many variables.
Given a partition \( \lambda \) of \( n \in \mathbb{N}_0 \), let
\[
\text{mon}_\lambda = \sum_{\alpha \vdash n \atop P(\alpha) = \lambda} x^\alpha,
\]
where \( P(\alpha) \) is the partition obtained by rearranging the parts of \( \alpha \) into weakly decreasing order. We say that \( \text{mon}_\lambda \) is the monomial symmetric function labelled by \( \lambda \). (The notation \( m_\lambda \) is more usual, but monomial symmetric functions are not so important, and \( m \) is a useful letter to have free.) For example, the basis of \( \Lambda_3 \) above is \( \text{mon}_{(3)} \), \( \text{mon}_{(2,1)} \), \( \text{mon}_{(1,1,1)} \). More generally,
\[
\{ \text{mon}_\lambda : \lambda \vdash n \}
\]
is a basis for \( \Lambda_n \). Thus the dimension of \( \Lambda_n \) is the number of partitions of \( n \). Note that \( \text{mon}_\emptyset = 1 \).

1.4. Elementary symmetric functions. While easily defined, the monomial basis is not the most useful for most computations. We shall now define several different bases, starting with the elementary symmetric functions, and see the first signs that the transition matrices between these bases are of combinatorial and algebraic interest.

For \( n \in \mathbb{N}_0 \) the elementary symmetric function of degree \( n \) is defined by
\[
e_n = \text{mon}_{(1^n)}.
\]
For example \( e_2 = x_1 x_2 + x_1 x_3 + x_2 x_3 + x_1 x_4 + \cdots \). For \( \mu \) a composition of \( n \) define \( e_\mu = e_{\mu_1} \cdots e_{\mu_{\ell(\mu)}} \). The \( e_\mu \) are called elementary symmetric functions.

**Lemma 1.2.** For \( \mu \) a partition of \( n \) define coefficients \( N_{\lambda \mu} \) by
\[
e_\mu = \sum_{\lambda \vdash n} N_{\lambda \mu} \text{mon}_\lambda.
\]
Then \( N_{\lambda \mu} \) is the number of \( 0 \)-\( 1 \) matrices with row sums \( \lambda \) and column sums \( \mu \).

**Proof.** The coefficient of \( \text{mon}_\lambda \) in \( e_\mu \) is equal to the number of ways to choose one monomial from each bracket in the product
\[
e_\mu = \prod_{j=1}^{\ell(\mu)} e_{\mu_j} = \prod_{j=1}^{\ell(\mu)} (x_{1}x_{2}\cdots x_{\mu_j} + \cdots)
\]
so that the product of all \( \ell(\mu) \) monomials is \( x^\lambda \). These choices correspond to \( 0 \)-\( 1 \) matrices \( Z \) of size \( \ell(\lambda) \times \ell(\mu) \) with row sums \( \lambda \) and column sums \( \mu \): if we choose \( x_{k_1}x_{k_2}\cdots x_{k_{\mu_j}} \) from the \( j \)th bracket we set \( Z_{kj} = \cdots = Z_{k_{\mu_j}j} = 1 \), and all other entries in column \( j \) of \( Z \) to be 0. Conversely, such a matrix clearly determines a corresponding choice of monomials. \( \square \)

For example,
\[
e_{(2,2)} = (x_1 x_2 + x_1 x_3 + x_2 x_3 + x_1 x_4 + \cdots)(x_1 x_2 + x_1 x_3 + x_2 x_3 + x_1 x_4 + \cdots)
\]
\[
= \text{mon}_{(2,2)} + 2 \text{mon}_{(2,1,1)} + 6 \text{mon}_{(1,1,1,1)}.
\]
The 0-1 matrices with row sums \((2, 1, 1)\) and column sums \((2, 2)\) corresponding to the summand \(2\text{mon}_{(2,1,1)}\) are
\[
\begin{pmatrix}
1 & 1 \\
1 & 0 \\
0 & 1
\end{pmatrix}, \quad
\begin{pmatrix}
1 & 1 \\
0 & 1
\end{pmatrix}.
\]

**Proposition 1.3.** The set \(\{e_\mu : \mu \vdash n\}\) is a basis for \(\Lambda_n\).

**Proof.** The ‘necessity’ direction of the Gale–Ryser Theorem says that if \(N_{\lambda\mu} \neq 0\) then \(\lambda' \succeq \mu\). Hence
\[
e_\mu = \sum_{\lambda' \succeq \mu} N_{\lambda\mu}\text{mon}_\lambda = \sum_{\nu \succeq \mu} N_{\nu'\mu}\text{mon}_{\nu'} = \sum_{\nu \succeq \mu} X_{\nu\mu}\text{mon}_{\nu'}
\]
where \(X_{\nu\mu} = N_{\nu'\mu}\). Note that \(X_{\nu\mu} = 0\) unless \(\nu \succeq \mu\). By Question 1(a), \(X_{\nu\mu} = N_{\nu'\mu} = 1\) for all partitions \(\mu\). Hence \(X\) is unitriangular and so invertible. \(\square\)

For example, we have
\[
(e_{4}, e_{3,1}, \ldots, e_{1}) = (\text{mon}_{(4)}, \text{mon}_{(2,1,1)}, \ldots, \text{mon}_{(4)})X
\]
where
\[
X = \begin{pmatrix}
1 & 4 & 6 & 12 & 24 \\
\cdots & 1 & 2 & 5 & 12 \\
\cdots & \cdots & 1 & 2 & 6 \\
\cdots & \cdots & \cdots & 1 & 4 \\
\cdots & \cdots & \cdots & \cdots & 1
\end{pmatrix}.
\]

Since \(X\) is upper triangular, so is \(X^{-1}\). Thus \((X^{-1})_{\nu\mu} \neq 0\) only if \(\nu \succeq \mu\). Multiplying (1.1) by \(X^{-1}\) we obtain
\[
\sum_{\mu \succeq \nu} (X^{-1})_{\mu\nu} e_\mu = \text{mon}_{\nu'}.
\]
Hence
\[
\text{mon}_\lambda = \sum_{\lambda' \succeq \nu} (X^{-1})_{\mu\nu} e_\mu.
\]
In particular, \(\text{mon}_\lambda = e_{\lambda'} + g\) where \(g\) is a linear combination of \(e_\mu\) for \(\mu \triangleright \lambda\). By the first equality in (1.1), when \(g\) is expressed in the monomial basis, each summand \(\text{mon}_v\) with a non-zero coefficient satisfies \(v' \triangleright \lambda'\), or equivalently, \(v \prec \lambda\). We have therefore recovered the traditional algorithm for writing a symmetric function \(f\) as a linear combination of elementary symmetric functions: find the lexicographically greatest monomial summand in \(f\) with a non-zero coefficient, say \(c\text{mon}_\lambda\), replace \(f\) with \(f - ce_{\lambda'}\), and repeat.

**Remark 1.4.** Working with the dominance order rather than the lexicographic order gives more information. For example, if \(g = \text{mon}_{(2,2,2)} - e_{(3,3)}\) then, when expressed in the monomial basis, \(g\) does not involve \(\text{mon}_{(3,1,1,1)}\), and when expressed in the basis of elementary symmetric functions, \(g\) does not involve \(e_{(3,1,1,1)} = e_{(4,1,1)}\).
1.5. Complete homogeneous symmetric functions. The complete homogeneous symmetric function of degree \( n \) is defined by \( h_n = \sum_{\lambda \vdash n} \text{mon}_{\lambda} \). By definition, \( h_n = \sum_{|a|=n} x^a \). For example,
\[
\begin{align*}
h_1 &= \text{mon}_{(1)} = x_1 + x_2 + \cdots \\
h_2 &= \text{mon}_{(2)} + \text{mon}_{(1,1)} = x_1^2 + x_1x_2 + x_1 + x_2 + x_3 + x_2x_3 + \cdots.
\end{align*}
\]

For \( \mu \) a composition of \( n \) define \( h_\mu = h_{\mu_1} \cdots h_{\mu_{\ell(\mu)}} \in \Lambda_n \). The \( h_\mu \) are called complete homogeneous symmetric functions.

We shall relate the \( h_\mu \) to the elementary symmetric functions defined in §1.4. For this it will be useful to work in the ring \( \hat{\mathbb{C}}[x_1, x_2, \ldots][[t]] \) of formal power series \( \sum_{n=0}^{\infty} f_n t^n \) with coefficients in \( \mathbb{C}[x_1, x_2, \ldots] \). A subring is the ring \( \Lambda[[t]] \) of formal power series with coefficients in \( \Lambda \). Let
\[
H(t) = \prod_{i=1}^{\infty} \frac{1}{1-x_i t} \in \hat{\mathbb{C}}[[t]].
\]
Observe that
\[
H(t) = \prod_{i=1}^{\infty} (1 + x_i t + x_i^2 t^2 + \cdots) = \sum_{n=0}^{\infty} h_n t^n.
\]
Hence \( H(t) \in \Lambda[[t]] \). Let \( E(t) = 1/H(t) \). We have
\[
E(t) = \prod_{i=1}^{\infty} (1 - x_i t) = \sum_{n=0}^{\infty} (-1)^n e_n t^n.
\]
Taking the coefficient of \( t^n \) in \( 1 = H(t)E(t) \) we obtain Newton’s Identity
\[
(1.2) \quad \sum_{k=0}^{n} (-1)^k e_k h_{n-k} = 0 \quad \text{if} \quad n \in \mathbb{N}.
\]

**Proposition 1.5.** The set \( \{ h_\mu : \mu \vdash n \} \) is a basis of \( \Lambda_n \).

**Proof.** Newton’s identity rearranges to \( h_n = \sum_{k=1}^{n} (-1)^{k-1} e_k h_{n-k} \). Thus \( h_n = (-1)^{n-1} e_n + f \) where \( f \) is in the polynomial algebra generated by \( e_1, \ldots, e_{n-1}, h_1, \ldots, h_{n-1} \). It follows by induction that \( h_n \in (-1)^{n-1} e_n + \mathbb{C}[e_1, \ldots, e_{n-1}] \). Hence
\[
h_\mu = \prod_{i=1}^{\ell(\mu)} (-1)^{\mu_i-1} e_{\mu_i} + f_i
\]
where each \( f_i \) is a linear combination of \( e_v \) for partitions \( v \) of \( \mu_i \) with at least two parts. Therefore
\[
(1.3) \quad h_\mu \in (-1)^{n-\ell(\mu)} e_\mu + \langle e_v : v \text{ is a proper refinement of } \mu \rangle.
\]

(A partition \( v \) is a proper refinement of a partition \( \mu \) if \( v \neq \mu \) and it is possible to add up parts of \( v \) to obtain \( \mu \), using each part of \( v \) exactly once. For example \((5,3,1,1)\) is a proper refinement of \((6,4)\) since \(6 =
5 + 1 and 4 = 3 + 1.) The matrix expressing the \( h_\mu \) in the basis \( \{ e_\nu : \nu \vdash n \} \) is therefore triangular with entries \( \pm 1 \) on the main diagonal. \( \square \)

See Question 6 on Problem Sheet 1 for some further properties of the matrix \( R \).

1.6. Specializations. Let \( N \in \mathbb{N} \). We define

\[ \hat{ev}_N : \tilde{C}[x_1, x_2, \ldots] \to C[x_1, \ldots, x_N] \]

by

\[ \hat{ev}_N(x^\alpha) = \begin{cases} x^\alpha & \text{if } \ell(\alpha) \leq N \\ 0 & \text{otherwise.} \end{cases} \]

It is clear from the definition of the product in \( \tilde{C}[x_1, x_2, \ldots] \) that \( \hat{ev}_N \) is a ring homomorphism. Let \( ev_N : \Lambda \to C[x_1, \ldots, x_N] \) be the restricted map. Thus if \( \lambda \) is a partition of \( n \) and \( \ell(\lambda) \leq N \) then

\[ ev_N(\text{mon} \lambda) = \sum_{\substack{\alpha \vdash n \\ \ell(\alpha) \leq N}} x^\alpha \]

while if \( \ell(\lambda) > N \) then \( ev_N(\text{mon} \lambda) = 0 \). From this formula we see that the image of \( ev_N \) is contained in the ring of symmetric polynomials in \( N \) variables \( C[x_1, \ldots, x_N]_{\text{Sym}N} \). As for \( \Lambda \), this ring is graded by degree. It is clear from the monomial basis for \( \Lambda_n \) that \( ev_N : \Lambda_n \to C[x_1, \ldots, x_N]_{\text{Sym}N} \) is always surjective, and injective if and only if only if \( N \geq n \).

We shall usually write \( f(x_1, \ldots, x_N) \) rather than \( ev_N(f) \). For example,

\[ e_2(x_1, x_2, x_3) = ev_3(x_1x_2 + x_1x_3 + x_2x_3 + x_1x_4 + \cdots) = x_1x_2 + x_1x_3 + x_2x_3, \]

\[ h_3(x_1, x_2) = ev_2(x_1^3 + \cdots + x_1^2x_2 + \cdots + x_1x_2x_3 + \cdots) = x_1^3 + x_2^3 + x_1^2x_2 + x_1x_2^2, \]

\[ e_3(x_1, x_2) = ev_2(x_1x_2x_3 + x_1x_2x_4 + \cdots) = 0 \]

More generally, \( ev_N(e_n) = 0 \) whenever \( N < n \). We can specialize further by sending each \( x_i \) for \( i \leq N \) to a given complex number \( z_i \in \mathbb{C} \). For example \( e_2(1, 1, 1) = 3 \) and \( h_3(1, 1) = 4 \).

Note that if \( f, g \in \Lambda \) then

\[ f = g \iff ev_N(f) = ev_N(g) \quad \text{for all } N \in \mathbb{N}. \tag{1.4} \]

Roughly put: a symmetric function is determined by its finite images.

1.7. Inverse limits*. The previous comment suggests that \( \Lambda \) could somehow be constructed out of the rings \( C[x_1, \ldots, x_N]_{\text{Sym}N} \). Consider the commutative diagram below.
The horizontal maps are determined by the commutativity: since $\text{ev}_N$ kills $x_{N+1}$, but not $x_N$, whereas $\text{ev}_{N-1}$ kills both, the map

$$q_N : C[x_1, \ldots, x_N]^\text{Sym}_N \rightarrow C[x_1, \ldots, x_{N-1}]^\text{Sym}_{N-1}$$

must be defined by $x_N \mapsto 0$ and $x_k \mapsto x_k$ for $k < N$. We record the images $\text{ev}_N(f) = f^{(N)}$ of $f \in \Lambda$ as a sequence

$$(f^{(N)})_{N=1}^\infty \in \prod_{N=1}^\infty C[x_1, \ldots, x_N]^\text{Sym}_N.$$ 

Since this sequence determines $f$, the ring $\Lambda$ is isomorphic to a subring of $\prod_{N=1}^\infty C[x_1, \ldots, x_N]^\text{Sym}_N$. Imposing the compatibility condition from the commutative diagram, we can identify this subring explicitly: the degree $n$ component is

$$\{(f^{(N)})_{N=1}^\infty \in \prod_{N=1}^\infty C[x_1, \ldots, x_N]^\text{Sym}_N : q_N(f^{(N)}) = f^{(N-1)} \text{ for all } N \geq 2\}.$$ 

This ring is the inverse limit $\varprojlim C[x_1, \ldots, x_N]^\text{Sym}_N$, defined using the maps $q_N$, taken in the category of graded rings.

**Remark 1.6.** It is essential to work with graded rings: let

$$f^{(N)} = e_1(x_1, \ldots, x_N) + \cdots + e_N(x_1, \ldots, x_N)$$

for each $N \in \mathbb{N}$ and let $(f^{(N)})_{N=1}^\infty \in \prod_{N=1}^\infty C[x_1, \ldots, x_N]^\text{Sym}_N$. This sequence satisfies the compatibility condition $q_N(f^{(N)}) = f^{(N-1)}$ but does not correspond to an element of $\Lambda$. I am grateful to Darij Grinberg for this example.

**Completions.** Let $R$ be a ring and let $I_N \triangleleft R$ for $N \in \mathbb{N}$ be ideals of $R$ such that $I_N \succeq I_{N+1}$ for each $N$. The completion of $R$ with respect to $(I_N)_{N=1}^\infty$ is $\hat{R} = \varprojlim R/I_N$, defined as a subring of $\prod_{N=1}^\infty R/I_N$ by

$$\hat{R} = \{(r_N + I_N)_{N=1}^\infty : r_N + I_{N-1} = r_{N-1} + I_{N-1} \text{ for all } N \geq 2\}.$$ 

It is useful to think of $r_N + I_N$ as the ‘$N$th approximation’ of the element $(r_N + I_N)_{N=1}^\infty \in \hat{R}$: since $I_N \succeq I_{N+1}$, these approximations get better and better as $N$ increases. If $R$ and the ideals $I_N$ are graded then, as suggested by the previous remark, one normally wants the graded completion, defined by $\tilde{R}_n = \varprojlim (R/I_N)_n$ for each $n$. 
Example 1.7.

1. The ring $\hat{C}[x_1, x_2, \ldots]$ defined in §1.3 is isomorphic to the graded completion of the polynomial ring $C[x_1, x_2, \ldots]$ with respect to the ideals $I_N = \ker \hat{ev}_N = \langle x_{N+1}, x_{N+2}, \ldots \rangle$. An eventually constant sequence corresponds to an element of $C[x_1, x_2, \ldots]$ and a sequence $(f^{(N)})_{N=1}^\infty$ where

$$f^{(N)} \in C[x_1, x_2, \ldots] / I_N \cong C[x_1, \ldots, x_N]$$

such that each $f^{(N)}$ is invariant under $\text{Sym}_N$ and has constant degree $n$ corresponds to an element of $\Lambda_n$.

Note that $\hat{C}[x_1, x_2, \ldots]_{\text{Sym}(N)} = \Lambda$, whereas $C[x_1, x_2, \ldots]_{\text{Sym}(N)} = C$. Thus taking fixed points does not commute with inverse limits and there is no sense in which $\Lambda$ is a completion of the ring $C[x_1, x_2, \ldots]_{\text{Sym}(N)}$.

2. The rings of formal power series $\hat{C}[[t]]$ and $\Lambda[[t]]$ are also examples of completions. Generally, for any ring $S$ we have $S[[t]] \cong \lim_{\leftarrow} S[t] / \langle t^N \rangle$.

3. Let $p$ be prime. The ring of $p$-adic integers $\mathbb{Z}_p$ is isomorphic to the completion $\lim_{\leftarrow} \mathbb{Z} / \langle p^N \rangle$. The similarity to (2) is not coincidental: the rings $\mathbb{Z}_p$ and $F[[t]]$, where $F$ is a field have many properties in common.

1.8. Counting compositions*. Let $n, N \in \mathbb{N}_0$. As an easy application of specializations we determine the number $C_n(N)$ of compositions $\alpha$ of $n$ such that $\ell(\alpha) \leq N$. Specialize $h_n$ so that $x_i \mapsto 1$ if $i \leq N$ and $x_i \mapsto 0$ if $i > N$ to get

$$\sum_{n=0}^{\infty} C_n(N) t^n = \sum_{n=0}^{\infty} h_n(1, \ldots, 1) t^n = \frac{1}{(1-t)^N} = \sum_{n=0}^{\infty} \binom{-N}{n} (-t)^n.$$

Hence

$$C_n(N) = \binom{-N}{n} (-1)^n = \frac{(-N)(-N-1) \ldots (-N-n+1)}{n!} (-1)^n = \frac{N(N+1) \ldots (N+n-1)}{n!} \binom{N+n-1}{n}.$$

(This trick of negating the top in a binomial coefficient is often useful when simplifying sums involving binomial coefficients.)

1.9. MacMahon’s Master Theorem*. The duality between the elementary and complete symmetric functions gives a slick proof of MacMahon’s Master Theorem (his name for it). The presentation below is based on a question of Alexander Chervov: see MathOverflow 103919.
**Lemma 1.8.** Let $B$ be a square matrix with entries in a polynomial ring $\mathbb{C}[x_1, \ldots, x_N]$. Working in $\mathbb{C}[x_1, \ldots, x_N][[t]]$, we have

$$\det(I - Bt)^{-1} = \sum_{n=0}^{\infty} \text{Tr} \text{Sym}^n(Bt).$$

**Proof.** Suppose that $B$ is an $M \times M$-matrix. It suffices to prove the identity with the indeterminates $x_1, \ldots, x_N$ specialized to $N$ arbitrary complex numbers. Let $B'$ be the specialized matrix and let $\theta_1, \ldots, \theta_M \in \mathbb{C}$ be its eigenvalues. By specializing $H(t) = \prod_{i=1}^{\infty} (1 - x_i t)^{-1} = \sum_{n=0}^{\infty} h_n t^n$ at $\theta_1, \ldots, \theta_M$ we get

$$\det(I - B't)^{-1} = \prod_{i=1}^{M} \frac{1}{1 - \theta_i t} = \sum_{n=0}^{\infty} h_n(\theta_1, \ldots, \theta_M) t^n.$$

Now observe that the eigenvalues of $\text{Sym}^n B'$ are exactly the monomials $\theta^\alpha = \theta_1^{\alpha_1} \cdots \theta_M^{\alpha_M}$ for $\alpha$ a composition of $n$ with $\ell(\alpha) \leq M$. \hfill \qed

**Example 1.9** (Dixon’s Identity). We shall show that

$$\sum_{k=0}^{2m} (-1)^k \binom{2m}{k}^3 = (-1)^m \frac{(3m)!}{m!^3}.$$

The left-hand side is

$$(*) \quad [x^{2m} y^{2m} z^{2m}] (x - y)^{2m} (y - z)^{2m} (z - x)^{2m}.
$$

where square brackets denote taking a coefficient, since if we take $x^k$ from $(x - y)^{2m}$ then we must also take $y^k$ from $(y - z)^{2m}$ and $z^k$ from $(z - x)^{2m}$. Consider the matrix

$$B = \begin{pmatrix} 0 & y & -z \\ -x & 0 & z \\ x & -y & 0 \end{pmatrix}$$

representing a linear transformation in a basis $u, v, w$ of the $\mathbb{C}[x, y, z]$-module $\mathbb{C}[x, y, z]^3$. Let $i + j + k = n$. We have

$$(\text{Sym}^n B)(u^i v^j w^k) = B(u)^i B(v)^j B(w)^k = (-xv + xw)(yu - yw)(zu + zw)^k = x^i y^j z^k (-v + w)^i (u - w)^j (-u + v)^k.$$}

Hence the coefficient of $x^{2m} y^{2m} z^{2m}$ in $\text{Tr} \text{Sym}^{6m} B$ is the coefficient of $u^{2m} v^{2m} w^{2m}$ in $(-v + w)^{2m} (u - w)^{2m} (-u + v)^{2m}$. The variables have changed, but the coefficient is the same as in $(*)$. Hence

$$\sum_{k=0}^{2m} (-1)^k \binom{2m}{k}^3 = [x^{2m} y^{2m} z^{2m}] \text{Tr} \text{Sym}^{6m} B.$$
On the other hand, since det \((I - Bt) = 1 + (xy + yz + zx)t^2\), Lemma 1.8 implies that the right-hand side is

\[
[x^{2m}y^{2m}z^{2m}t^6] \det(I - Bt)^{-1} = [x^{2m}y^{2m}z^{2m}t^6](1 + (xy + yz + zx)t^2)^{-1}
\]

\[
= [x^{2m}y^{2m}z^{2m}]( -1)^m(xy + yz + zx)^{3m}.
\]

If we take \((xy)^k\) from the multinomial expansion of \((xy + yz + zx)^{3m}\), we must then take \((yz)^{2m-k}\) to get the correct power of \(y\), and then \((xz)^m\) to get a monomial of the correct degree. Therefore the only contribution to the coefficient of \(x^{2m}y^{2m}z^{2m}\) comes from taking each of \(xy, yz\) and \(zx\) exactly \(m\) times. Hence the coefficient is \((-1)^m(3m)!/m!^3\), as claimed.

The general result is as follows.

**Theorem 1.10** (MacMahon’s Master Theorem). Let \(A\) be an \(N \times N\) complex matrix and let \(B = A \text{ diag}(x_1, \ldots, x_N)\). Thus the entries of \(B\) lie in \(\mathbb{C}[x_1, \ldots, x_N]\). Let \(y_1, \ldots, y_N\) be \(N\) further indeterminates. If \(\alpha \vdash n\) and \(\ell(\alpha) \leq N\) then

\[
[x^\alpha t^n] \det(I - Bt)^{-1} = [y^\alpha] \prod_{i=1}^N (\sum_{j=1}^N A_{ji}y_j)^{\alpha_i}.
\]

**Proof.** By Lemma 1.8, it is equivalent to show that

\[
[x^\alpha] \text{Tr Sym}^n B = [y^\alpha] \prod_{i=1}^N (\sum_{j=1}^N A_{ji}y_j)^{\alpha_i}.
\]

Let \(v_1, \ldots, v_N\) be a basis of the \(\mathbb{C}[x_1, \ldots, x_N]\)-module \(\mathbb{C}[x_1, \ldots, x_N]^N\). Since the only variable appearing in the \(i\)th column of \(B\) is \(x_i\), the left-hand side is the coefficient of \(v^n\) in \(\prod(Av_i)^{\alpha_i}\). Since \(Av_i = \sum_{j=1}^N A_{ji}v_j\), this agrees with the right-hand side.

See Questions 6 and 7 for some further applications of MacMahon’s Master Theorem.

1.10. **Power sum symmetric functions.** For \(n \in \mathbb{N}\), we define \(p_n = \text{mon}_1(n) = \sum_{i=1}^\infty x_i^n \in \Lambda_n\). Let \(p_0 = 1\). For \(\alpha\) a composition of \(n\) define \(p_\alpha = p_{\alpha_1} \cdots p_{\alpha_{\ell(\alpha)}}\). We say that \(p_\alpha\) is the **power sum symmetric function** corresponding to \(\alpha\). To prove that the power sum symmetric functions labelled by partitions form a basis for \(\Lambda\) we adapt the argument using Newton’s Identity seen earlier.

Let \(Q(t) = \sum_{n=1}^\infty p_n t^n / n\). Observe that

\[
Q(t) = \sum_{n=1}^\infty \sum_{i=1}^\infty \frac{x_i^n t^n}{n} = -\sum_{i=1}^\infty \log(1 - x_i t).
\]

Hence

\[
\exp Q(t) = \prod_{i=1}^\infty \frac{1}{1 - x_i t} = H(t).
\]
By Question 3(c), we have the identity \( tH'(t) = tQ'(t)H(t) \). Taking coefficients of \( t^n \) gives the Newton type identity

\[(1.6) \quad nh_n = \sum_{k=1}^{n} p_k h_{n-k}.\]

Hence \( p_n = nh_n - \sum_{k=1}^{n-1} p_k h_{n-k} \). It follows as in §1.5 that \( C[p_1, \ldots, p_n] = C[h_1, \ldots, h_n] \) for all \( n \) and that \( \{p_\alpha : \alpha \vdash n\} \) is a basis of \( \Lambda_n \).

We make the following remarks.

(1) Let \( n \in \mathbb{N} \) and let \( \Lambda_{Z,n} = \{\sum_{\alpha \vdash n} c_\alpha \text{mon}_\alpha : c_\alpha \in \mathbb{Z}\} \). Since the transition matrix from \( \{e_\mu : \mu \vdash n\} \) to \( \{\text{mon}_\alpha : \alpha \vdash n\} \) is unitriangular (see Proposition 1.3), we obtain the same set if we replace each \( \text{mon}_\alpha \) with \( e_\Lambda \). However, the subgroup

\[\{\sum c_\alpha p_\alpha : c_\alpha \in \mathbb{Z}\}\]

of \( \Lambda_n \) is properly contained in \( \Lambda_{Z,n} \). For example, \( e_2 = \frac{1}{2}(p_1^2 - p_2) = \frac{1}{2}p_{(1,1)} - \frac{1}{2}p_2 \), so this subgroup contains \( 2e_2 \), but not \( e_2 \).

Informally, we say that the \( p_\alpha \) do not form a \( \mathbb{Z} \)-basis for \( \Lambda_n \).

(2) Suppose that \( f(p_1, \ldots, p_m) = 0 \), where \( f \in \mathbb{C}[y_1, \ldots, y_m] \). Let

\[f(y_1, \ldots, y_m) = \sum_{\beta} c_\beta y_1^{\beta_1} \cdots y_m^{\beta_m}\]

where the sum is over all compositions \( \beta \) with \( \ell(\beta) \leq m \). Substituting \( p_k \) for \( y_k \) for each \( k \in \{1, \ldots, m\} \), we get

\[\sum_{\beta} c_\beta p_{(\beta_1, \ldots, \beta_m)} = 0.\]

Since the \( p_\lambda \) for \( \lambda \) a partition form a basis for \( \Lambda \), we see that \( c_\beta = 0 \) for all \( \beta \). Hence \( f = 0 \) and \( p_1, p_2, \ldots \) are algebraically independent. An analogous result holds for \( e_1, e_2, \ldots \) and \( h_1, h_2, \ldots \).

1.11. The cycle index of the symmetric group*. We have

\[\exp Q(t) = \exp \sum_{k=1}^{\infty} \frac{p_k t^k}{k} = \prod_{k=1}^{\infty} \exp \frac{p_k t^k}{k} = \prod_{k=1}^{\infty} \sum_{m=0}^{\infty} \frac{p_k^m}{k^m m!}.\]

Let \( \alpha \) be a partition of \( n \) having exactly \( a_k \) parts of size \( k \) for each \( k \in \{1, \ldots, n\} \). There is a unique way to obtain \( p_\alpha t^n \) by multiplying out the right-hand side above; the coefficient of \( p_\alpha t^n \) is \( \prod_{k=1}^{n} 1/(k^{a_k} a_k!) \). Therefore

\[(1.7) \quad \exp Q(t) = \sum_{n=0}^{\infty} \sum_{\alpha \vdash n} \frac{p_\alpha t^n}{z_\alpha}\]

where, by definition,

\[z_\alpha = \prod_{k=1}^{n} k^{a_k} a_k!.\]
This proves the following result.

**Theorem 1.11 (Cycle Index Formula).**

\[
\exp \sum_{k=1}^{\infty} \frac{p_k}{k} t^k = \sum_{n=0}^{\infty} \frac{p_n}{n!} t^n = \sum_{n=0}^{\infty} \frac{1}{(n^{a_1}, \ldots, 1^{a_n})-n} \frac{1^{a_1} \cdots n^{a_n} a_1! \cdots a_n!}{n!} t^n.
\]

Note that by (1.5), the left-hand side is \( \prod_{i=1}^{\infty} (1 - x_i t) = \sum_{n=0}^{\infty} h_n t^n \).

By Question 8, \( z_\alpha \) is the order of the centralizer in \( \text{Sym}_n \) of an element of cycle-type \( \alpha \). Thus there are \( n!/z_\alpha \) such elements in \( \text{Sym}_n \), and \( 1/z_\alpha \) is the probability of picking one, when permutations are chosen uniformly at random. Therefore a restatement of the Cycle Index Formula is

\[
\exp \sum_{k=1}^{\infty} \frac{p_k}{k} t^k = \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{\sigma \in \text{Sym}_n} p_{\rho(\sigma)} t^n
\]

\[
= \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{\sigma \in \text{Sym}_n} p_1^{\text{cyc}_1(\sigma)} \cdots p_n^{\text{cyc}_n(\sigma)} t^n
\]

(1.8)

where the partition \( \rho(\sigma) \) is the cycle-type of \( \sigma \in \text{Sym}_n \) and \( \text{cyc}_m(\sigma) \) is the number of \( m \)-cycles in \( \sigma \).

Many appealing results can be obtained by specializing the Cycle Index Formula by setting the \( p_n \) to particular complex numbers or indeterminates. This is justified by the algebraic independence of the \( p_n \).

In the following result, recall that \( \sigma \in \text{Sym}_n \) is a derangement if \( \sigma \) has no fixed points.

**Corollary 1.12.**

(i) Let \( d_n \) be the number of derangements in \( \text{Sym}_n \). Then

\[
\frac{d_n}{n!} = 1 - \frac{1}{1!} + \frac{1}{2!} - \cdots + \frac{(-1)^n}{n!}.
\]

(ii) Let \( O_n \) be the number of derangements in \( \text{Sym}_n \) that have an odd number of cycles, and let \( E_n \) be the number of derangements in \( \text{Sym}_n \) that have an even number of cycles. Then \( O_n - E_n = n - 1 \).

(iii) Let \( o_n \) be the number of derangements in \( \text{Sym}_n \) that are odd permutations, and let \( e_n \) be the number of derangements in \( \text{Sym}_n \) that are even permutations. Then \( o_n - e_n = (-1)^n (n - 1) \).

**Proof.** Let \( D_n \) be the set of derangements in \( \text{Sym}_n \). For (i) and (ii) specialize the version of the Cycle Index Formula in (1.8) by setting \( p_1 = 0 \) and \( p_k = z \) for \( k \geq 2 \), where \( z \) is an indeterminate. We get

\[
\exp \sum_{k=2}^{\infty} \frac{z t^k}{k} = \sum_{n=0}^{\infty} \frac{t^n}{n!} \sum_{\sigma \in D_n} z^{\text{cyc}(\sigma)}
\]
where \( \text{cyc}(\sigma) \) is the number of cycles in \( \sigma \). Setting \( z = 1 \) we get

\[
\frac{\exp(-t)}{1-t} = \exp(-t - \log(1-t)) = \sum_{n=0}^{\infty} \frac{d_n}{n!} t^n.
\]

Taking the coefficient of \( t^n \) on the left-hand side gives (i). For (ii) set \( z = -1 \) to get

\[
(1-t) \exp t = \exp(t + \log(1-t)) = \sum_{n=0}^{\infty} \frac{E_n - O_n}{n!} t^n
\]

and again take the coefficient of \( t^n \). Part (iii) is left as an exercise: see Question 9.

\( \square \)

1.12. \textbf{Asymptotics of cycles}. Treat the \( p_k \) in (1.8) as formal indeterminates. Observe that if we differentiate (1.8) with respect to \( p_m \) we obtain

\[
\frac{t^m}{m} \exp \sum_{k=1}^{\infty} \frac{p_k k^k}{k!} = \sum_{n=0}^{\infty} \frac{t^n}{n!} \sum_{\sigma \in \text{Sym}_n} \text{cyc}_m(\sigma) p_m^{\text{cyc}_m(\sigma)-1} \prod_{k \neq m} p_k^{\text{cyc}_k(\sigma)}.
\]

Specialize by setting \( p_k \) to 1 for all \( k \) to get

\[
\frac{t^m}{m} \frac{1}{1-t} = \sum_{n=0}^{\infty} \frac{t^n}{n!} \sum_{\sigma \in \text{Sym}_n} \text{cyc}_m(\sigma).
\]

Taking the coefficient of \( t^n \), we see that the mean number of \( m \)-cycles in a permutation in \( \text{Sym}_n \) is \( 1/m \) if \( n \geq m \), and otherwise zero.

More generally, let \( \beta \) be a composition of \( \beta_1 + 2\beta_2 + \cdots = b \) and differentiate \( \beta_m \) times with respect to \( p_m \) for each \( m \), to obtain

\[
\frac{t^b}{\prod_{m \in \mathbb{N}} m^{\beta_m}} \exp \sum_{k=1}^{\infty} \frac{p_k k^k}{k!} = \sum_{n=0}^{\infty} \frac{t^n}{n!} \prod_{\sigma \in \text{Sym}_n} \prod_{m \in \mathbb{N}} \beta_m! \left( \frac{\text{cyc}_m(\sigma)}{\beta_m} \right) \prod_{k \neq m} p_k^{\text{cyc}_k(\sigma)-\beta_k}.
\]

Specialize by setting \( p_k = 1 \) for all \( k \) to get

\[
\frac{t^b}{\prod_{m \in \mathbb{N}} m^{\beta_m}} \frac{1}{1-t} = \sum_{n=0}^{\infty} \frac{t^n}{n!} \prod_{\sigma \in \text{Sym}_n} \prod_{m \in \mathbb{N}} \beta_m! \left( \frac{\text{cyc}_m(\sigma)}{\beta_m} \right).
\]

Taking the coefficient of \( t^n \) it follows that

\[
\text{E} \left[ \prod_{m \in \mathbb{N}} \left( \frac{\text{cyc}_m(\sigma)}{\beta_m} \right) \right] = \frac{1}{z_{(1^{\beta_1}, 2^{\beta_2}, \ldots)}} \quad \text{for all } n \geq b
\]

where the expected value is taken over all permutations \( \sigma \in \text{Sym}_n \), chosen uniformly at random. (Here \( (1^{\beta_1}, 2^{\beta_2}, \ldots) \) denotes the partition with exactly \( \beta_m \) parts of size \( m \), for each \( m \in \mathbb{N} \).)

Below we write \( \text{cyc}_m^{(n)}(\sigma) \) for \( \text{cyc}_m(\sigma) \) when \( \sigma \in \text{Sym}_n \).
Theorem 1.13 (Goncharov). As \( n \to \infty \) the random variables \( \cyc_m^{(n)} \) converge to independent Poisson random variables with mean \( 1/m \).

Outline proof: The binomial moments of a Poisson random variable \( X \) with mean \( \gamma \) are \( \mathbb{E}[(X)^r] = \gamma^r/r! \). Let \( C_m \) for \( m \in \mathbb{N} \) be independent Poisson random variables with mean \( 1/m \). By independence we have
\[
\mathbb{E} \left[ \prod_{m \in \mathbb{N}} \left( C_m^{\beta_m} \right) \right] = \frac{1}{z(1^{\beta_1}, 2^{\beta_2}, \ldots)}
\]
for all compositions \( \beta \) of \( n \). Comparing with (1.9) we see that if \( \beta \) is a composition of \( b \) then
\[
\mathbb{E} \left[ \prod_{m \in \mathbb{N}} C_m^{\beta_m} \right] = \mathbb{E} \left[ \prod_{m \in \mathbb{N}} (\cyc_m^{(n)})^{\beta_m} \right] \quad \text{for all } n \geq b.
\]
It follows that the moments of the \( \cyc_m^{(n)} \) converge to the moments of the \( C_m \) as \( n \to \infty \). This implies convergence in joint distribution. \( \square \)

1.13. Schur functions. Recall that \([\lambda]\) denotes the Young diagram of a partition \( \lambda \).

Definition 1.14. Let \( \lambda \) be a partition of \( n \). A \( \lambda \)-tableau is a function \([\lambda] \to \mathbb{N}\). To draw a \( \lambda \)-tableau \( t \), draw the Young diagram of \( \lambda \) and, for each \((i, j) \in [\lambda]\), put \( t(i, j) \) inside the corresponding box. A \( \lambda \)-tableau is semistandard if its rows are weakly increasing (from left to right) and its columns are strictly increasing (from top to bottom). Let \( \text{SSYT}(\lambda) \) be the set of all semistandard \( \lambda \)-tableaux. Given a \( \lambda \)-tableau \( t \), let \( c_k(t) = \left| \{(i, j) \in [\lambda] : t(i, j) = k \} \right| \). The content of \( t \) is the composition \((c_1(t), c_2(t), \ldots)\). For a \( \alpha \) a composition of \( n \), let \( \text{SSYT}(\lambda, \alpha) \) be the set of \( \lambda \)-tableaux with content \( \alpha \). Define
\[
x^t = x_1^{c_1(t)} x_2^{c_2(t)} \ldots
\]
The Schur function \( s_\lambda \) is then defined by
\[
s_\lambda = \sum_{t \in \text{SSYT}(\lambda)} x^t.
\]
For example,
\[
s(3) = x^{\frac{111}{}} + x^{\frac{112}{}} + x^{\frac{122}{}} + x^{\frac{123}{}} + \cdots
\]
\[
= x^3 + x_1^2 x_2 + x_1 x_2^2 + x_1 x_2 x_3 + \cdots
\]
\[
= \text{mon}(3) + \text{mon}(2,1) + \text{mon}(1,1,1).
\]
Notice that if we specialize to three variables then \( x^t = 0 \) whenever \( t \) has an entry strictly greater than 3. So

\[
s_{(2,1)}(x_1, x_2, x_3)
= x_1 + x_2 + x_3
= x_1^2 x_2 + x_1 x_2 x_3 + x_1 x_2 x_3
= \text{mon}_{(2,1)}(x_1, x_2, x_3) + 2\text{mon}_{(1,1,1)}(x_1, x_2, x_3).
\]

Since \( \text{ev}_3 : \Lambda_3 \rightarrow C[x_1, x_2, x_3]^{\text{Sym}_3} \) is injective, it follows, on the assumption that \( s_{(2,1)} \) is a symmetric function, that \( s_{(2,1)} = \text{mon}_{(2,1)} + 2\text{mon}_{(1,1,1)} \).

**Lemma 1.15.** Let \( n \in \mathbb{N} \). Then \( s_{(n)} = h_n \) and \( s_{(1^n)} = e_n \).

**Proof.** This follows easily from the definition of semistandard. \( \square \)

Note that in every case seen so far \( s_{\lambda} \) is a symmetric function. This is not obvious from our definition, but has a beautiful short proof due to Bender and Knuth.

**Proposition 1.16.** The Schur functions are symmetric functions.

**Proof.** Let \( \lambda \) be a partition and let \( i \in \mathbb{N} \). It suffices to define an involution \( \text{BK} : \text{SSYT}(\lambda) \rightarrow \text{SSYT}(\lambda) \) such that \( x^{\text{BK}(t)} = x^t(i, i + 1) \). (More explicitly, if \( x^t = g x_{i+1}^t \) where \( g \) is a monomial not involving \( x_i \) or \( x_{i+1} \), then \( x^{\text{BK}(t)} = g x_{i+1}^t \).) For it then follows that

\[
s_{\lambda} = \sum_{t \in \text{SSYT}(\lambda)} x^t = \sum_{t \in \text{SSYT}(\lambda)} x^{\text{BK}(t)} = \sum_{t \in \text{SSYT}(\lambda)} x^t(i, i + 1) = s_{\lambda}(i, i + 1)
\]

and so \( s_{\lambda} \) is invariant under all transpositions, and so invariant under all finitary permutations (i.e. permutations fixing all but finitely many elements of \( \mathbb{N} \)). It is an easy exercise to show that if \( f \in \hat{C}[x_1, x_2, \ldots] \) is fixed by all finitary permutations then \( f \in \Lambda \). Therefore \( s_{\lambda} \in \Lambda \).

Let \( t \in \text{SSYT}(\lambda) \). With minor changes for the top and bottom rows, the \( is \) and \((i + 1)s \) in \( t \) in each row of \( t \) are arranged as shown below:

<table>
<thead>
<tr>
<th></th>
<th>\cdots</th>
<th></th>
<th>\cdots</th>
<th></th>
<th>\cdots</th>
</tr>
</thead>
<tbody>
<tr>
<td>(i)</td>
<td>(i)</td>
<td>(i)</td>
<td>(i)</td>
<td>(i+1)</td>
<td>(i+1)</td>
</tr>
<tr>
<td>(i+1)</td>
<td>(i+1)</td>
<td>(i+1)</td>
<td>(i+1)</td>
<td>(i+1)</td>
<td>(i+1)</td>
</tr>
</tbody>
</table>

Define \( \text{BK}(t) \) by replacing the \( a is \) and \( b (i + 1)s \) in the middle part of each row with \( b is \) and \( a (i + 1)s \). The new tableau clearly has weakly increasing rows, and the columns are strictly increasing because the entries below the middle part are \( > i + 1 \) and the entries above the middle part are \( < i \). \( \square \)
It follows that if $\lambda$ is a partition of $n$ then
\begin{equation}
(1.10) \quad s_\lambda = \sum_{\mu \vdash n} |\text{SSYT}(\lambda, \mu)| \text{mon}_\mu.
\end{equation}

By Question 11, $\text{SSYT}(\lambda, \mu) = \emptyset$ unless $\lambda \supseteq \mu$. Moreover $|\text{SSYT}(\lambda, \lambda)| = 1$. By the standard argument it follows that $\{s_\lambda : \lambda \vdash n\}$ is a basis for $\Lambda_n$. An alternative proof of this fundamental result is given in §2. We remark that the Kostka Numbers $K_{\lambda \mu}$ are defined by $K_{\lambda \mu} = |\text{SSYT}(\lambda, \mu)|$.

\section{The Jacobi–Trudi Identity}

In this section we shall see how to express the Schur functions in the basis of complete homogeneous symmetric functions.

\textbf{Theorem 2.1} (Jacobi–Trudi Identity). Let $\lambda$ be a partition of $n$ and let $M \geq \ell(\lambda)$. Then
\begin{equation}
 s_\lambda = \det \begin{pmatrix}
 h_{\lambda_1} & h_{\lambda_1+1} & \cdots & h_{\lambda_1+(M-1)} \\
 h_{\lambda_2-1} & h_{\lambda_2} & \cdots & h_{\lambda_2+(M-2)} \\
 \vdots & \vdots & \ddots & \vdots \\
 h_{\lambda_{M-(M-1)}} & h_{\lambda_{M-(M-2)}} & \cdots & h_{\lambda_M}
\end{pmatrix}
\end{equation}
where we set $h_r = 0$ if $r < 0$.

We offer a ‘proof by example’ that shows all the main features of the general proof, outlined in Question 12.

\textbf{Example 2.2.} Take $\lambda = (5,3,3)$ and $M = 3$. We prove that the Jacobi–Trudi Identity holds for $s_\lambda$ when both sides are evaluated at $x_1, \ldots, x_5$. Let $B_i = (3 - i + \lambda_i, 5)$ for $i \in \{1,2,3\}$. Consider the diagram below.

![Diagram showing the grid and paths](image)

Marked on the grid is a triple of paths $(P_3, P_2, P_1)$ such that $P_i$ goes from $(3 - i, 1)$ to $B_i$ for each $i$. (Note that $P_3$ is strictly left of $P_2$, which is strictly left of $P_1$; this remains true in the general case where $B_i = (M - i + \lambda_i, 5)$, for each $i$.) Let $S$ be the set of all such triples, like the one shown above, where no two paths intersect.
Claim. The map sending the \((5,3,3)\)-tableau \(t\) with entries \(a_1 \leq \ldots \leq a_{\lambda_i}\) in row \(i\) to the triple \((P_3, P_2, P_1)\) where \(P_i\) has horizontal steps at heights \(a_1, \ldots, a_{\lambda_i}\) is a bijection between the set of semistandard \((5,3,3)\)-tableaux with entries from \(\{1,2,3,4,5\}\) and \(S\).

Proof. Let \((P_3, P_2, P_1)\) correspond to the tableau \(t\). Suppose paths \(P_i\) and \(P_{i+1}\) meet, for the first time, at \((a,b)\). Then \(P_{i+1}\) goes from \((a-1,b)\) to \((a,b)\), say in its \(r\)th rightward step, and \(P_i\) goes from \((a,b-1)\) to \((a,b)\) and makes its \(r\)th rightward step at \((a,c)\) for some \(c \geq b\). Hence \(t(i,r) = c \geq b = t(i+1,r)\), so \(t\) is not semistandard. The converse is similar and is left as an exercise. \(\Box\)

Let \(A\) be the set of all triples of paths \((P_3, P_2, P_1)\) such that \(P_i\) goes from \((3-i,1)\) to \(B_i\), for some permutation \(\tau \in \text{Sym}_3\). We now allow paths to intersect: if \(\tau \neq \text{id}\) then at least one intersection is inevitable.

An example where \(\tau = (1,2)\) is shown below.

Define the weight of a path \(P_i\) with horizontal steps at heights \(h_1, \ldots, h_r\) by \(\text{wt}(P_i) = x_{h_1} \ldots x_{h_r}\). Thus the path \(P_2\) from \((1,1)\) to \((7,5)\) drawn in blue above has weight \(x_1x_2^2x_4x_5^2\). Define the weight of a triple \((P_3, P_2, P_1)\) by \(\text{wt}(P_3, P_2, P_1) = \text{wt}(P_3)\text{wt}(P_2)\text{wt}(P_1)\). Define the sign of a triple \((P_3, P_2, P_1)\) where each \(P_i\) ends at \(B_i\) to be \(\text{sgn}(\tau)\). For the triple shown above we have \(\text{wt}(P_3, P_2, P_1) = x_1x_2x_3^2x_4^2x_5^2\) and \(\text{sgn}(P_3, P_2, P_1) = -1\).

The previous claim shows that

\[
(2.1) \quad \text{ev}_{S_\lambda} = \sum_t x^t = \sum_{(P_3, P_2, P_1) \in S} \text{wt}(P_3, P_2, P_1)
\]

where the middle sum is over all semistandard \(\lambda\)-tableaux with entries from \(\{1,2,3,4,5\}\).

Claim. Let \(P \in A \setminus S\). Choose \(i\) minimal so that \(P_i\) meets another path. Follow \(P_i\), starting at \((M-i,1)\) and stepping up and right, until it meets another path, at a point \((a,b)\). Let \(j\) be maximal such that \(P_j\) passes through \((a,b)\). Let \(P_i\) agree with \(P_i\) until this intersection and then follow \(P_j\). Similarly let \(P_j\) agree with \(P_j\) until this intersection and then
follow $P_i$. Let $\overline{P}_k = P_k$ if $k \neq i, j$. Define $J : A \to A$ by

$$J(P_3, P_2, P_1) = \begin{cases} (P_3, \overline{P}_2, \overline{P}_1) & \text{if } (P_3, P_2, P_1) \in A \setminus S \\ (P_3, P_2, P_1) & \text{otherwise.} \end{cases}$$

Then $J$ is a weight-preserving involution on $A$ fixing exactly the triples in $S$. Moreover, $J$ is sign-reversing on $A \setminus S$.

Proof. Let $(P_3, P_2, P_1) \in A \setminus S$ and let $i$ and $j$ be as above. In $(P_3, P_2, P_1)$, the positions of intersections do not change; the paths involved in each intersection change only when one or both was originally $P_i$ or $P_j$ and afterwards $\overline{P}_i$ or $\overline{P}_j$. Therefore $i$ is still minimal such that $\overline{P}_i$ meets another path, the first intersection point is still $(a, b)$, and $j$ is still maximal such that $\overline{P}_j$ passes through $(a, b)$.

Hence $J$ is an involution. If $\tau$ is the permutation for $(P_3, P_2, P_1)$ then, since the final destinations of the paths starting at $(M - i, 1)$ and $(M - j, 1)$ are swapped, $(i, j)\tau$ is the permutation for $(P_3, \overline{P}_2, \overline{P}_1)$. Hence $J$ is sign-reversing on $A \setminus S$. Since the right steps in $P_3, P_2, P_1$ and $\overline{P}_3, \overline{P}_2, \overline{P}_1$ occur at the same heights, $J$ is weight-preserving. □

For example, let $(P_3, P_2, P_1)$ be the intersecting paths above. The image $(\overline{P}_3, \overline{P}_2, \overline{P}_1)$ under $J$ is shown below. We have $i = 1$, $j = 2$ and $(a, b) = (3, 3)$.

![Diagram](image)

By pairing up $(P_3, P_2, P_1)$ and $J(P_3, P_2, P_1)$ for each $(P_3, P_2, P_1) \in A \setminus S$, and observing that their contributions to the left-hand side of the equation below cancel, we get

$$\sum_{(P_3, P_2, P_1) \in A} \text{wt}(P_3, P_2, P_1) \text{sgn}(P_3, P_2, P_1) = \sum_{(P_3, P_2, P_1) \in S} \text{wt}(P_3, P_2, P_1).$$
The right-hand side is \( \text{ev}_{5 \lambda} \) by (2.1). So to complete the proof, we need to show that

\[
\sum_{(P_3, P_2, P_1) \in A} \text{wt}(P_3, P_2, P_1) \text{sgn}(P_3, P_2, P_1) = \text{ev}_{5} \det \begin{pmatrix} h_5 & h_6 & h_7 \\ h_2 & h_3 & h_4 \\ h_1 & h_2 & h_3 \end{pmatrix}
\]

\[
= \text{ev}_{5}(h_{(5,3,3)} - h_{(5,2,4)} + h_{(1,6,4)} - h_{(2,6,3)} + h_{(2,2,7)} - h_{(1,3,7)}).
\]

This is easily checked: for example, the summand \( h_{(2,6,3)} = h_{(6,3,2)} \) enumerates the weighted paths from (2, 1) to (4, 5), (1, 1) to (7, 5) and (0, 1) to (3, 5), with 2, 6 and 3 steps right, respectively.

The general result on how summands in the expansion of the determinant correspond to path tuples can be guessed from this example: see Question 12. See also Lemma 4.9 and the following remark for the connection with the dot action.

**Corollary 2.3.** Let \( n \in \mathbb{N}_0 \). There exist \( L_{\lambda\mu} \in \mathbb{Z} \) for \( \lambda, \mu \vdash n \) such that

\[
s_\lambda = \sum_{\mu \vdash n} L_{\lambda\mu} h_\mu.
\]

Moreover \( L_{\lambda\mu} = 0 \) unless \( \mu \succeq \lambda \) and \( L_{\lambda\lambda} = 1 \) for all \( \lambda \) and \( \mu \).

**Proof.** Let \( \ell(\lambda) = M \). Suppose we expand the determinant of the \( M \times M \) matrix in the Jacobi–Trudi Identity for \( s_\lambda \) by taking \( h_{\lambda_i - i + c_i} \) from row \( i \). This gives a contribution to the coefficient of \( h_\mu \) where \( \mu \) is the partition obtained by rearranging the entries of \( (\lambda_1 - 1 + c_1, \ldots, \lambda_k - k + c_k) \) into decreasing order. We have

\[
\sum_{i=1}^{j} \mu_i \geq \sum_{i=1}^{j} (\lambda_i - i + c_i) = \sum_{i=1}^{j} \lambda_i + \sum_{i=1}^{j} (c_i - i) \geq \sum_{i=1}^{j} \lambda_i
\]

where the final inequality holds because \( \{c_1, \ldots, c_k\} = \{1, \ldots, k\} \). Hence \( \mu \succeq \lambda \). Moreover, if \( \mu = \lambda \) then \( c_i = i \) for each \( i \) (since if \( j \) is minimal such that \( c_j > j \) then we have strict inequality above) and so \( L_{\lambda\lambda} = 1 \). \( \square \)

The matrix expressing the \( s_\lambda \) for \( \lambda \) a partition of \( n \) in the basis \( \{h_\mu : \mu \vdash n\} \) of \( \Lambda_n \) is therefore triangular with diagonal entries 1. It follows, by the usual argument, that \( \{s_\lambda : \lambda \vdash n\} \) is a basis for \( \Lambda_n \). (A more standard proof using the monomial basis was indicated at the end of §1.13.)

**Corollary 2.4.** Let \( 0 \leq m \leq n/2 \). Then

(i) \( s_{(n-m,m)} = h_{(n-m,m)} - h_{(n-m+1,m-1)} \)

(ii) \( h_{(n-m,m)} = s_{(n-m,m)} + \cdots + s_{(n-1,1)} + s_{(n)} \).

**Proof.** By the Jacobi–Trudi Identity we have

\[
s_{(n-m,m)} = \det \begin{pmatrix} h_{n-m} & h_{n-m+1} \\ h_{m-1} & h_m \end{pmatrix} = h_{(n-m,m)} - h_{(n-m+1,m-1)}.
\]

This proves (i). Part (ii) then follows by induction, using \( s_{(n)} = h_{(n)} \) for the base case. \( \square \)
3. ANTISYMMETRIC FUNCTIONS AND THE ABACUS

Fix $N \in \mathbb{N}$ throughout this section. We define an $N$-strict partition to be a partition $(\beta_1, \ldots, \beta_N)$ such that $\ell(\beta) \leq N$ and $\beta_1 > \ldots > \beta_N$. Thus the partition $(4, 2, 1, 0, \ldots)$ is 3-strict and 4-strict. We write $\beta \vdash_N n$ to denote that $\beta$ is an $N$-strict partition of $n$.

3.1. Antisymmetric functions. Let

$$\Gamma = \{ f \in \mathbb{C}[x_1, \ldots, x_N] : f \sigma = f \operatorname{sgn}(\sigma) \text{ for all } \sigma \in \operatorname{Sym}_N \}.$$ 

Let $\Gamma_n = \{ f \in \Gamma : f \text{ is homogeneous of degree } n \}$ and note that $\Gamma = \bigoplus_{n \in \mathbb{N}_0} \Gamma_n$. Given a $N$-strict partition $\beta$ of $n$, we define

$$a_\beta = \det \begin{pmatrix} x_1^{\beta_1} & \ldots & x_N^{\beta_1} \\ \vdots & \ddots & \vdots \\ x_1^{\beta_N} & \ldots & x_N^{\beta_N} \end{pmatrix}.$$ 

Observe that

$$(3.1) \quad a_\beta = \sum_{\sigma \in \operatorname{Sym}_N} x_1^{\beta_1} \ldots x_N^{\beta_N} \sigma \operatorname{sgn}(\sigma)$$

so $a_\beta \in \Gamma_n$. Since the leading term (i.e. the lexicographically greatest monomial summand) in $a_\beta$ is $x_1^{\beta_1}$, it follows that $\{ a_\beta : \beta \vdash_N n \}$ is a basis for $\Gamma_n$. Define

$$(3.2) \quad \delta = (N - 1, N - 2, \ldots, 1, 0).$$

Observe that if $\beta \vdash_N n$ then $\beta$ has $N$ distinct parts (including perhaps 0) and so $\beta - \delta$ is a partition. Hence the basis of $\Gamma_n$ above is $\{ a_{\lambda+\delta} : |\lambda + \delta| = n, \ell(\lambda) \leq N \}$.

If $\beta$ is an $N$-strict partition then $a_\beta$ specializes to 0 if we set $x_i = x_j$ for distinct $i$ and $j$. By unique factorization, $a_\beta$ is divisible by $\prod_{i < j} (x_i - x_j)$. Then, as a special case of this remark,

$$a_\delta = \det \begin{pmatrix} x_1^{N-1} & \ldots & x_N^{N-1} \\ \vdots & \ddots & \vdots \\ x_1 & \ldots & x_N \\ 1 & \ldots & 1 \end{pmatrix}$$

is divisible by $\prod_{i < j} (x_i - x_j)$. Since each $x_i$ has degree $N - 1$ in the product, and also in $a_\delta$, and both the product and $a_\delta$ have leading term $x_1^{\delta}$, equality holds. Therefore each $a_\beta$ is divisible by $a_\delta$ and $a_{\lambda+\delta}/a_\delta$ is a non-zero polynomial for each $\lambda$ with $\ell(\lambda) \leq N$.

Remark 3.1. We show in Theorem 4.10 that

$$(3.3) \quad \frac{a_{\lambda+\delta}}{a_\delta} = s_\lambda(x_1, \ldots, x_N)$$

for any partition $\lambda$ with $\ell(\lambda) \leq N$. For a slightly direct proof, in the spirit of this section, see Question 24.
3.2. The abacus. Let \( \lambda \) be a partition. The *rim* of \( \lambda \) consists of all boxes \((i, j) \in [\lambda]\) such that \((i + 1, j + 1) \notin [\lambda]\). Imagine walking along the rim of \( \lambda \), starting in the SW corner with coordinate \((0, \lambda'_1)\) and ending at the NE corner at coordinate \((\lambda_1, 0)\). For each step right, put a *gap* \( \circ \), and for each step right, put a *bead* \( \bullet \). For example, the rim of \((3, 3, 1)\) is encoded by \( \circ \bullet \circ \circ \circ \bullet \circ \), as shown below.

![Abacus Diagram](image)

**Definition 3.2.** An *abacus* for \( \lambda \) is any sequence obtained by taking the sequence of beads and gaps encoding the rim of \( \lambda \), then prepending any number of beads, and appending any number of gaps. Beads before the first gap are said to be *initial*; gaps after the final bead are said to be *final*.

We number the positions in abaci from 0. For example the abacus \( \bullet \circ \bullet \circ \circ \bullet \circ \circ \circ \) represents \((3, 3, 1)\), and has beads in positions 0, 2, 5, 6. The bead in position 0 is initial and the gaps in positions 7 and 8 are final. The abacus \( \bullet \bullet \circ \circ \) represents the empty partition \( \emptyset \). Clearly a partition can be reconstructed from any of its abaci. The abacus representation for partitions is due to G. D. James: see [5, page 78] for a textbook account.

The following definition is key to the approach in this section. It is due to Loehr [8].

**Definition 3.3.** Let \( \lambda \) be a partition with \( \ell(\lambda) \leq N \). Fix an abacus for \( \lambda \) with exactly \( N \) beads and no final gaps. A *labelled abacus* for \( \lambda \) is any sequence obtained from this abacus by replacing each gap with 0 and each bead with a unique element of \( \{1, \ldots, N\} \). Let \( \text{Abc}(\lambda) \) be the set of labelled abaci for \( \lambda \).

The \( N \) relevant to \( \text{Abc}(\lambda) \) will always be clear from the context. We write labelled abaci as words, as shown in Example 3.4 immediately below. Let \( \lambda \) be a partition. The symmetric group \( \text{Sym}_N \) acts transitively on \( \text{Abc}(\lambda) \) by

\[
(A \sigma)_i = \begin{cases} 
0 & \text{if } A_i = 0 \\
A_i \sigma & \text{if } A_i \neq 0.
\end{cases}
\]

Let \( A(\lambda) \in \text{Abc}(\lambda) \) be the unique labelled abacus whose non-zero entries are decreasing.

**Example 3.4.** Let \( N = 3 \). The unique 3 bead abacus for \((3, 1)\) with no final gap is \( \bullet \circ \bullet \circ \circ \bullet \). Thus \( A(3, 1) = 302001 \) and

\[
\text{Abc}(3, 1) = \{302001, 301002, 203001, 201003, 103002, 102003\}.
\]
If $\sigma = (1, 2, 3) \in \text{Sym}_3$ then $302001 \sigma = 103002$. Observe that $x_3^0 x_2^2 x_1^5$ is the leading term in $a_{(3,1)+(2,1,0)}$, and that

$$a_{(3,1)+(2,1,0)} = x_2^2 x_1^5 - x_1^2 x_2^5 + x_3^2 x_1^5 - x_1^2 x_3^5 + x_3^2 x_2^5 - x_2^2 x_3^5 = \sum_{\sigma \in \text{Sym}_3} x_2^2 x_1^5 \sigma \text{ sgn}(\sigma)$$

The example shows why the freedom to have initial beads in abaci is important. It also motivates the following definition and lemma.

**Definition 3.5.** Let $A \in \text{Abc}(\lambda)$. The *weight* of $A$ is $\prod_{i=1}^{N} x_i^{\alpha_i}$ where $\alpha_i$ is the position of $A$ containing $i$. We write $\text{wt}(A)$ or $x^A$ for the weight of $A$.

The *sign* of $A$ is $\text{sgn}(A) = \sigma \in \text{Sym}_N$ is the unique permutation such that $A(\lambda) \sigma = A$. We write $\text{sgn}(A)$ for the sign of $A$.

**Lemma 3.6.** Let $\lambda$ be a partition. Then

$$a_{\lambda+\delta} = \sum_{A \in \text{Abc}(\lambda)} x^A \text{ sgn}(A).$$

**Proof.** An unlabelled $N$ bead abacus for $\lambda$ has beads in positions $\lambda_i + N - i$ for each $i \in \{1, \ldots, N\}$; these are the entries of $\lambda + \delta$. Hence

$$a_{\lambda+\delta} = \sum_{\sigma \in \text{Sym}_N} x_1^{\lambda_1+(N-1)} \cdots x_N^{\lambda_N} \sigma \text{ sgn}(\sigma)$$

$$= \sum_{\sigma \in \text{Sym}_N} x^{A(\lambda)} \sigma \text{ sgn}(\sigma)$$

$$= \sum_{A \in \text{Abc}(\lambda)} x^A \text{ sgn}(A)$$

as required. \qed

### 3.3. Pieri’s Rule

Given a partition $\lambda$ of $n$ and $r \in \mathbb{N}_0$, we define $P_r(\lambda) = \{ \mu \vdash n + r : [\mu] \text{ is obtained from } [\lambda] \text{ by adding } r \text{ boxes, no two in the same row}\}$.

**Theorem 3.7** (Pieri’s Rule). Let $\lambda$ be a partition of $n$ and let $r \in \mathbb{N}_0$. Then

$$a_{\lambda+\delta} e_r(x_1, \ldots, x_N) = \sum_{\mu \in P_r(\lambda)} a_{\mu+\delta}.$$

For example, if $N = 3$ we have

$$a_{(1,1)+\delta} e_r(x_1, x_2, x_3) = a_{(2,2)+\delta} + a_{(2,1,1)+\delta}.$$

Like the proof of the Jacobi–Trudi Identity, the proof uses a sign-reversing involution.

**Proof.** Let

$$\mathcal{P} = \{(A, S) : A \in \text{Abc}(\lambda), S \subseteq \{1, \ldots, N\}, |S| = r\}.$$
For \((A, S) \in \mathcal{P}\) define \(\text{wt}(A, S) = x^A \prod_{i \in S} x_i\) and \(\text{sgn}(A, S) = \text{sgn}(A)\). Thus the left-hand side of the claimed identity is
\[
\sum_{(A, S) \in \mathcal{P}} \text{wt}(A, S) \text{sgn}(A, S).
\]
This sum usually involves some cancellation. For example, if \(\lambda = (1, 1)\) and \(r = 2\) then the summands for \(\{3021, \{2, 3\}\}\) and \(\{3012, \{1, 3\}\}\), namely \(x^2_2 x^3_1 x^2_2 x^3_3\) and \(-x_2^2 x^3_1 x_1 x^3_3\), cancel. To capture this we define a sign-reversing involution \(J : \mathcal{P} \to \mathcal{P}\). Given \((A, S) \in \mathcal{P}\), read \(A\) right to left, and try to move each bead labelled by an element of \(S\) one step right in \(A\). There are two cases:

- If there are no collisions, a new labelled abacus \(B\) is obtained.
  With labels removed, \(B\) represents a partition \(\mu \in P_r(\lambda)\). Since \(B\) has no final gaps, we have \(B \in \text{Abc}(\mu)\). Define \(J(A, S) = (A, S)\) and \(K(A, S) = B\).
- Suppose that the first collision occurs when bead \(j\) is moved onto bead \(k\). Then \(j \in S\) and \(k \notin S\). Define \(J(A, S) = (A(j, k), S(j, k))\).

The following claims are fairly easy to check:

1. \(J\) is an involution. \textit{Proof}: suppose \(J(A, S) = (A(j, k), S(j, k))\) as above. Then when we move beads in \(A(j, k)\) the first collision occurs when bead \(k \in S(j, k)\) bumps bead \(j\).

2. \(J\) is weight-preserving. \textit{Proof}: suppose \(J(A, S) = (A(j, k), S(j, k))\) as above and that the bead labelled \(j\) is in position \(a\). Then the bead labelled \(k\) is in position \(a + 1\). Let \(g = \prod_{k} x^a_k\) where the product is over all \(k \in \{1, \ldots, N\}\) such that \(k \neq i, j\) and \(a_k\) is the position of \(A\) containing \(k\). We have
\[
\text{wt}(A, S) = x^a_j x^{a+1}_k g \prod_{i \in S} x_i
\]
\[
= x^{a+1}_j x^{a+1}_k g \prod_{i \in S, i \neq j} x_i
\]
\[
= x^{a+1}_j x^{a+1}_k g \prod_{i \in S(j,k), i \neq k} x_i
\]
\[
= x^{a+1}_j x^{a+1}_k g \prod_{i \in S(j,k)} x_i
\]
\[
= \text{wt}(A(j, k), S(j, k)).
\]

3. \(J\) is sign-reversing on its non-fixed points.

4. \(K\) is a bijection between the set of fixed points of \(J\) and the set \(\bigcup_{\mu \in P_r(\lambda), \ell(\mu) \leq N} \text{Abc}(\mu)\). \textit{Proof}: each such partition \(\mu\) can be obtained in a unique way by moving \(r\) beads on an (unlabelled) \(N\)-bead abacus for \(\lambda\) one step to the right. (Note that only partitions with at most \(N\) parts can be obtained, because only \(N\)
beads are present.) Hence, passing to labelled abaci, $K$ is bijective.

(5) $K$ is weight-preserving. **Proof:** if $K(A, S) = B$ then each bead in $A$ labelled by $j \in S$ is moved one step to the right in $B$, so $x^B = x^A \prod_{i \in S} x_i = \text{wt}(A, S)$.

(6) $K$ is sign-preserving. **Proof:** If $K(A, S) = B$ then the bead labels appear in the same order in $A$ and $B$.

Hence

$$a_{\lambda+\delta} e_r(x_1, \ldots, x_N) = \sum_{(A, S) \in P} \text{wt}(A, S) \text{sgn}(A, S)$$

$$= \sum_{(A, S) \in P} \text{wt}(A, S) \text{sgn}(A, S)$$

$$= \sum_{\mu \in \mathcal{P}_r(\lambda)} \sum_{B \in \text{abc}(\mu)} \text{wt}(B) \text{sgn}(B)$$

$$= \sum_{\mu \in \mathcal{P}_r(\lambda)} a_{\mu+\delta},$$

where the second equality holds by (1), (2), (3) and the third by (4), (5) and (6).

**3.4. Young’s Rule.** Given a partition $\lambda$ of $n$ and $r \in \mathbb{N}_0$, let $Y_r(\lambda) = \{\mu \vdash n + r : [\mu]$ is obtained from $[\lambda]$ by adding $r$ boxes, no two in the same column$\}$.

**Theorem 3.8 (Young’s Rule).** Let $\lambda$ be a partition of $n$ and let $r \in \mathbb{N}_0$. Then

$$a_{\lambda+\delta} h_r(x_1, \ldots, x_N) = \sum_{\mu \in Y_r(\lambda)} a_{\mu+\delta}. \quad \square$$

A highly recommended exercise (see Question 16) is to prove Young’s Rule in a similar way to Pieri’s Rule, replacing the sets $S$ with multisets. The key idea is to define $J(A, S)$ and the sequence of bead moves so that we have the analogues of (1) and (2) above: if bead $j$ bumps bead $k$ in the moves for $(A, S)$ then bead $k$ should bump bead $j$ in the moves for $J(A, S)$, and $\text{wt}(A, S) = \text{wt}(J(A, S))$.

**Corollary 3.9.** Let $\alpha$ be a composition of $n$. Then

$$h_\alpha(x_1, \ldots, x_N) = \sum_{\lambda \vdash n} |\text{SSYT}(\lambda, \alpha)| a_{\lambda+\delta}. \quad \square$$

**Proof.** Multiplying by $a_{\delta}$ it is equivalent to prove that the coefficient of $a_{\lambda+\delta}$ in the antisymmetric polynomial $a_{\delta} h_\alpha(x_1, \ldots, x_N)$ is $|\text{SSYT}(\lambda, \alpha)|$. By Theorem 3.8, this coefficient is the number of ways to obtain $\lambda$ from $\emptyset$ by performing Young’s Rule additions of $\alpha_1$ boxes, then $\alpha_2$ boxes, and so on. Labelling the added boxes by $i$ we see this is $|\text{SSYT}(\lambda, \alpha)|$. \quad \square
For example, if \( a = (3, 2, 1) \) and \( N = 3 \) then, abusing notation by writing \( h_r \) for \( h_r(x_1, x_2, x_3) \), we have

\[
a_{\delta} \ev_3(h_{(3,2,1)}) = a_{\delta} h_3 h_2 h_1 = (a_{(3,+) + \delta}) h_2 h_1 = (a_{(5,+) + \delta} + a_{(4,1,+) + \delta}) h_1 = (a_{(6,+) + \delta} + a_{(5,1,+) + \delta}) h_1 + (a_{(4,2,+) + \delta} + a_{(3,3,+) + \delta}) h_1.
\]

Thus the coefficient of \( a_{(4,2,+) + \delta} \) is 2, corresponding to the semistandard tableau

\[
\begin{array}{|c|c|c|c|}
\hline
1 & 1 & 2 \\
\hline
2 & 3 \\
\hline
\end{array}
\quad\quad
\begin{array}{|c|c|c|c|}
\hline
1 & 1 & 1 & 3 \\
\hline
2 & 2 \\
\hline
\end{array}
\]

Remark 3.10. Recall that \( P(a) \) is the partition obtained from the composition \( a \) by rearranging the parts into decreasing order. By Proposition 1.16, which was proved using the Bender–Knuth involution, if \( \lambda \) is a partition of \( n \) and \( \alpha, \beta \) are compositions of \( n \) such that \( P(\alpha) = P(\beta) \) then \( |\SSYT(\lambda, a)| = |\SSYT(\lambda, \beta)| \). Since \( h_\alpha = h_\beta \), Corollary 3.9 gives an alternative proof of this fact.

3.5. Hooks. Let \( \lambda \) be a partition. Fix an unlabelled abacus representing \( \lambda \). Moving a bead in position \( b \) to a gap in position \( b + r \) corresponds to adding \( r \) boxes to the rim of \( \lambda \). For an example see Figure 1 overleaf. If the new partition is \( \mu \), then we say that \( \mu / \lambda \) is an \( r \)-hook. The height of the \( r \)-hook \( \mu / \lambda \), denoted \( \ht(\mu / \lambda) \) is one less than the number of rows in the Young diagram of \( [\mu] \) that it meets. Equivalently \( \ht(\mu / \lambda) \) is the number of beads strictly between positions \( b \) and \( b + r \). We define the sign of \( \mu / \lambda \) by \( \sgn(\mu / \lambda) = (-1)^{\ht(\mu / \lambda)} \).

Theorem 3.11. Let \( \lambda \) be a partition of \( n \) with \( \ell(\lambda) \leq N \) and let \( r \in \mathbb{N} \). Then

\[
a_{\lambda + \delta} p_r(x_1, \ldots, x_N) = \sum_{\substack{\mu \vdash n + r \\
\ell(\mu) \leq N \\
\mu / \lambda \text{-hook}}} \sgn(\mu / \lambda) a_{\mu + \delta}.
\]

Proof. The proof follows the same model as the proof of Pieri’s rule. Let

\[
P = \{(A, j) : A \in Abc(\lambda), j \in \{1, \ldots, N\}\}.
\]

For \( (A, j) \in P \) define \( wt(A, j) = x^A x_j^r \) and \( \sgn(A, j) = \sgn(A) \). By construction

\[
a_{\lambda + \delta} p_r(x_1, \ldots, x_N) = \sum_{(A, j) \in P} \sgn(A, j) \ wt(A, j).
\]

As before, this sum involves some cancellation. For example, let \( \lambda = (3,1), r = 3 \) and \( N = 3 \); the summands for \((302001, 2)\) and \((301002, 1)\),
FIGURE 1. Adding a 7-hook to $(6, 4, 3, 1, 1)$ by moving the bead $b$ in the abacus \( \bullet \bullet \bullet \bullet \bullet \bullet \bullet \) from position 2 to position 9 gives an abacus representing the partition $(6, 5, 5, 5, 4)$. The new gap in position 2 means we step right (adding a new box) rather than up; we then follow the rim of \( \lambda \) (making the same steps as before, but in the process adding a new box each time) until the new bead in position 9 means we step up rather than right, after walking around the rim of 7 added boxes.

namely \( x^2_2 x^5_1 x^3_2 \) and \( -x^2_1 x^5_2 x^3_1 \), cancel. We capture this cancellation by a sign-reversing involution \( J \) and a bijection \( K \).

Let \((A, j) \in \mathcal{P}\) and suppose the bead labelled \( j \) is in position \( b \).

- If there is a gap in position \( b + r \) then define \( J(A, j) = (A, j) \) and \( K(A, j) = B \) where \( B \) is the labelled abacus obtained from \( A \) by moving the bead labelled \( j \) to position \( b + r \). (This may require some 0s to be appended to \( A \).)
- Otherwise define \( J(A, j) = (A(j, k), k) \) where \( k \) is the label of the bead in position \( b + r \).

Then (1) \( J \) is an involution, (2) \( J \) is weight-preserving (the example above shows the idea) and (3) \( J \) is sign-reversing on its non-fixed points. Moreover we have the analogues of (4) and (5): \( K \) is a weight-preserving bijection

\[
\{(A, j) \in \mathcal{P} : J(A, j) = (A, j)\} \rightarrow \bigcup_{\substack{\mu, \nu, r \in \mathcal{P} \\ r \leq N \nu, \ell(\mu) \leq N \mu / \lambda \text{-hook}}} \text{Abc}(\mu).
\]

Finally suppose that \( K(A, j) = B \) where \( B \) represents \( \mu \). If \( \text{ht}(\mu / \lambda) = h \) then there are exactly \( h \) beads between the bead labelled \( j \) in \( A \) and the gap \( r \) positions to its right. As noted above, \( \text{sgn}(\mu / \lambda) = (-1)^h \). If these beads are labelled \( i_1, \ldots, i_h \) then the bead labels, read from left to right, are

\[
\ldots, j, i_1, \ldots, i_h \ldots \quad \text{in } A
\]

\[
\ldots, i_1, \ldots, i_h, j \ldots \quad \text{in } B.
\]
Hence if \( \sigma, \tau \in \text{Sym}_N \) are the permutations such that \( A(\lambda)\sigma = A \) and \( A(\mu)\tau = B \) then
\[
\tau = \sigma(j, i_1, \ldots, i_h).
\]
Since an \((h + 1)\)-cycle has sign \((-1)^h\), we have \(\text{sgn}(A) = (-1)^h \text{sgn}(B)\). Hence \(\text{sgn}(B) = \text{sgn}(A)(-1)^h = \text{sgn}(A) \text{sgn}(\mu/\lambda)\). Applying \(K\) to the fixed points of \(J\) we get
\[
a_{\lambda+\delta}p_r(x_1, \ldots, x_N) = \sum_{(A,j) \in P} \text{sgn}(A,j) \text{wt}(A,j)
= \sum_{B \in \text{Abc}(\mu)} \text{sgn}(\mu/\lambda) \text{sgn}(B) x^B
= \sum_{\mu} \text{sgn}(\mu/\lambda) a_{\mu+\delta}
\]
where the sums over \(\mu\) are as in the statement of the theorem. \[\square\]

As for Young’s Rule there is an equivalent version of the Murnaghan-Nakayama rule for multiplication of an antisymmetric polynomial by a general power sum symmetric polynomial. We need the following definition. In it we abuse notation slightly by writing \(\lambda \subseteq \mu\) to mean \([\lambda] \subseteq [\mu]\).

**Definition 3.12.** Let \(\lambda \vdash n\) and let \((\alpha_1, \ldots, \alpha_k) \models n\). A **border-strip tableau** of shape \(\lambda\) and type \(\alpha\) is a sequence of partitions
\[
\emptyset = \lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \ldots \subseteq \lambda^{(t)} = \lambda
\]
such that \(\lambda^{(i)}/\lambda^{(i-1)}\) is an \(\alpha_i\)-hook for each \(i\). The **sign** of this border-strip tableau is \(\prod_{i=1}^t \text{sgn}(\lambda^{(i)}/\lambda^{(i-1)})\). Define
\[
c^\lambda(\alpha) = \sum_T \text{sgn}(T)
\]
where the sum is over all border-strip tableaux \(T\) of shape \(\lambda\) and type \(\alpha\).

For example, there are four border-strip tableaux of shape \((3,2,1)\) and type \((1,2,2,1)\). They are shown below with the hook corresponding to the \(i\)th part of \(\alpha\) labelled \(i\). The signs are 1, -1, -1, 1, so we have \(c^{(3,2,1)}(1,2,2,1) = 0\).

\[
\begin{array}{c|c|c|c|c}
1 & 2 & 2 & 1 & 3 \\
3 & 3 & 2 & 4 & 2 \\
4 & 3 & 2 & 2 & 2 \\
\end{array}
\]

**Corollary 3.13.** Let \(\alpha\) be a composition of \(n\).
\[
p_\alpha(x_1, \ldots, x_N) = \sum_{\mu \vdash \ell(\mu) \leq N} c^\lambda(\alpha) \frac{a_{\lambda+\delta}}{a_\delta}.
\]
Proof. This follows in the same way as Corollary 3.9 by multiplying $a_\delta$ by $p_\alpha$ using Theorem 3.11. □

It follows, again as in Young’s Rule, that if $\lambda$ is a partition of $n$ and $\alpha$ and $\beta$ are compositions of $n$ such that $P(\alpha) = P(\beta)$ then $c^1(\alpha) = c^1(\beta)$. This gives a quicker way to see that $c^1(3,2,1)(1,2,2,1) = 0$: just observe that $P(1,2,2,1) = (2,2,1,1)$ and that $(3,2,1)$ has no 2-hooks.

On the symmetric group side $c^1(\lambda)$ is the value of the irreducible character of $\text{Sym}_n$ labelled by $\lambda$ on elements of cycle-type $\alpha$: see §5.5.

For some further corollaries of the Murnaghan–Nakayama rule see Questions 17 and 19. An alternative proof is outlined in Questions 20 and 21.

4. THE LASCOUX–SCHÜTZENBERGER INVOLUTION

The coplactic maps in this section were defined in [10, §5.5] (where they are called ‘coplactic operations’). For further background see [7]. The exposition here is essentially a greatly expanded version of [12]. The proofs of Lemmas 4.2 and 4.4 are adapted from [18].

4.1. Words. A word is an element of $N^*$, the free monoid on $N$. The word of a tableau $t$, denoted $w(t)$, is obtained by reading the rows of $t$ from bottom to top, left to right in each row. For example

$$w\left(\begin{array}{cccc}
1 & 1 & 2 & 3 \\
2 & 3 & 3 & 4 \\
4 & 5 
\end{array}\right) = 45233411233.$$

Note that if $t$ is semistandard then $w(t)$ determines the shape of $t$, and so $t$ itself.

**Definition 4.1.** Let $k \in N$ and let $w \in N^*$. A $k$ in $w$ is $k$-unpaired if when $w$ is read from left to right, this $k$ sets a new record for the excess of $ks$ over $(k+1)s$. Dually, a $k + 1$ in $w$ is $k$-unpaired if when $k$ is read right to left, this $k + 1$ sets a new record for the excess of $(k+1)s$ over $ks$. The $k$-unpaired subword of $w$ is the subword of unpaired entries. A $k$ or $k + 1$ in $w$ is $k$-paired if it is not $k$-unpaired.

We may omit the ‘$k$-’ in $k$-paired or $k$-unpaired if it will be clear from the context.

A useful way to identify the $k$-unpaired entries of a word $w$ is to replace each $k + 1$ in $w$ with a left parenthesis ‘(’ and each $k$ in $w$ with a right parenthesis ‘)’.

Then a $k$ or $k + 1$ is paired if and only if its parenthesis has a pair, according to the usual rules of bracketing. That this method works can be proved by strong induction on the length of $w$: if every $k$ is to the left of every $k + 1$ then all parentheses are unpaired, otherwise $w$ has a subword of the form $k + 1n\ell$ where $\ell$ contains no $k$ or $k + 1$; then $k + 1$ and $k$ correspond to paired parentheses and removing
the subword \( k + 1\) of \( w \) gives a shorter word to which the inductive hypothesis applies. For example, if \( w = 45233411233 \) is the word above, then underlining unpaired parentheses:

- If \( k = 1 \) the parenthesised word is \( 45(334)(33) \). The unpaired subword is 12 in positions 8 and 9 and removing 2341 gives a word with only unpaired parentheses.
- If \( k = 2 \) the parenthesised word is \( 45(411) \). The unpaired subword is 233, in positions 3, 10 and 11.

**Lemma 4.2.** Let \( w \in \mathbb{N}^* \) and let \( k \in \mathbb{N} \). The \( k \)-unpaired subword of \( w \) is of the form \( k^c(k+1)^d \) for some \( c, d \in \mathbb{N}_0 \). Changing the letters of this subword so that it becomes \( k^{c'}(k+1)^{d'} \) where \( c' + d' = c + d \) gives a new word whose \( k \)-unpaired entries are in the same positions as the \( k \)-unpaired entries of \( w \).

**Proof.** There cannot be an unpaired \( k \) to the right of an unpaired \( k + 1 \) in \( w \). Therefore all \( k \)s after the rightmost unpaired \( k + 1 \) are paired. Similarly there cannot be an unpaired \( k + 1 \) to the left of an unpaired \( k \) in \( w \), so all \( (k + 1) \)s before the leftmost unpaired \( k \) are paired. Hence the unpaired subword is as claimed.

When \( d \geq 1 \), changing the letters of the unpaired subword from \( k^c(k+1)^d \) to \( k^{c+1}(k+1)^{d-1} \) replaces the leftmost unpaired \( k + 1 \), in position \( i \) say, with a \( k \); since every \( k + 1 \) to the left of position \( i \) is paired, this new \( k \) is unpaired. The dual result holds when \( c \geq 1 \); together these imply the lemma. \( \square \)

For an immediate application of Lemma 4.2 see Question 23, which gives a short proof of Theorem 15.14 in [6].

**Definition 4.3.** Let \( w \in \mathbb{N}^* \), let \( k \in \mathbb{N} \) and suppose that \( w \) has \( k \)-unpaired subword \( k^c(k+1)^d \). Let \( S_k(w) \) be the word obtained from \( w \) by changing the letters of the \( k \)-unpaired subword to \( k^d(k+1)^c \). If \( d > 0 \), let \( E_k(w) \) be defined similarly, changing the subword to \( k^{c+1}(k+1)^{d-1} \). If \( c > 0 \), let \( F_k(w) \) be defined similarly, changing the subword to \( k^{c-1}(k+1)^{d+1} \).

By Lemma 4.2, \( E_k \) and \( F_k \) are mutual inverses and \( S_k \) is self-inverse.

### 4.2. Coplactic operations on tableaux

Using the word map \( w \) we can extend the definition of \( k \)-unpaired and the maps \( E_k, F_k \) and \( S_k \) to tableaux of a fixed shape. Thus an entry of a \( \mu \)-tableau \( t \) is \( k \)-unpaired if and only if it corresponds to a \( k \)-unpaired letter in \( w(t) \), \( E_k(t) \) is the unique \( \mu \)-tableau with word \( E_k(w(t)) \), and so on. For example, if

\[
  t = \begin{array}{cccc}
    1 & 1 & 1 & 2 & 3 \\
    2 & 3 & 4 & 4
  \end{array}
\]

then the 3-unpaired entries of \( t \) are in positions (2,2) and (2,3) and...
To motivate part of the next lemma, observe that $S_3E_3$ acts as an involution on the four tableaux with a 3-unpaired 4. Let

$$e(k) = (0, \ldots, 1, -1, \ldots, 0) \in \mathbb{Z}^N,$$

where the unique non-zero entries are in positions $k$ and $k + 1$.

**Lemma 4.4.** Let $\mu$ be a partition and let $\alpha$ be a composition with $\ell(\alpha) \leq N$. Fix $k \in \{1, \ldots, N - 1\}$. Let $SSYT_k(\mu, \alpha)$ and $SSYT_{k+1}(\mu, \alpha)$ be the sets of all semistandard tableaux of shape $\mu$ and content $\alpha$ that have a $k$-unpaired $k$ or a $k$-unpaired $k + 1$, respectively. Let $\alpha' = (\alpha_1, \ldots, \alpha_{k+1}, \alpha_{k}, \ldots, \alpha_N)$. The maps

$$E_k : SSYT_{k+1}(\mu, \alpha) \rightarrow SSYT_k(\mu, \alpha + e(k))$$

$$F_k : SSYT_k(\mu, \alpha) \rightarrow SSYT_{k+1}(\mu, \alpha - e(k))$$

$$S_k : SSYT_k(\mu, \alpha) \rightarrow SSYT_{k+1}(\mu, \alpha')$$

are bijections and the composition $S_kE_k : SSYT_{k+1}(\mu, \alpha) \rightarrow SSYT_{k+1}(\mu, \alpha' - e(k))$ is an involution.

**Proof.** The main thing to check is that if $t \in SSYT_{k+1}(\mu, \alpha)$ then $t' = E_k(t)$ is semistandard. Suppose that the leftmost unpaired $k + 1$ in $w(t)$ corresponds to the entry $(a, b)$ in position $(a, b)$ of $t$; this entry is changed to $k$ in $t'$. If $t'$ is not semistandard then $t(a-1, b) = k$. This $k$ is to the right of the unpaired $k + 1$ in $w(t)$, so by Lemma 4.2 it is paired, necessarily with a $k + 1$ in row $a$ and some column $b' > b$ of $t$. Since

$$k = t(a-1, b) \leq t(a-1, b') < t(a, b') = k + 1$$

we have $t(a-1, b') = k$. Thus $t(a, c) = k + 1$ and $t(a-1, c) = k$ for all $c \in \{b, \ldots, b'\}$. It follows that the entries in positions $(a - 1, b + j)$ and $(a, b' - j)$ of $t$ are paired for each $j \in \{0, 1, \ldots, b' - b\}$.

<table>
<thead>
<tr>
<th></th>
<th>col $b$</th>
<th>col $b'$</th>
</tr>
</thead>
<tbody>
<tr>
<td>row $a - 1$</td>
<td>$k$</td>
<td>$\cdots$</td>
</tr>
<tr>
<td>row $a$</td>
<td>$k + 1$</td>
<td>$\cdots$</td>
</tr>
</tbody>
</table>

In particular, the $k + 1$ in position $(a, b)$ of $t$ is paired, a contradiction. Hence $E_k(t)$ is semistandard. The proof is similar for $F_k$, in the case when $t$ has an unpaired $k$. 
It is now routine to check that $E_k F_k$ and $F_k E_k$ are the identity maps on their respective domains, so $E_k$ and $F_k$ are bijective. If the unpaired subword of $w(t)$ is $k^c(k + 1)^d$ then $S_k(t) = E_k^{d-c}(t)$ if $d \geq c$ and $S_k(t) = F_k^{d-c}(t)$ if $c \geq d$. Hence $S_k$ and $S_k E_k$ are involutions. It is easily checked that the image of $S_k E_k$ is as claimed. □

The final part of the claim gives some motivation for the next definition.

4.3. Dot action. The symmetric group $\text{Sym}_N$ acts on $\mathbb{Z}^N$ by place permutation: thus if $\alpha \in \mathbb{Z}^N$ and $\sigma \in \text{Sym}_N$ then $(\alpha \sigma)_k = a_{kr-1}$. Note that the entry $a_k$ in position $k$ of $\alpha$ appears in position $k \sigma$ of $\alpha \sigma$. This shows why the inverse appears in the definition; without it, the action is not well-defined.

We define the dot action of $\text{Sym}_N$ on $\mathbb{Z}^N$ by
\begin{equation}
\alpha \cdot (k, k + 1) = \alpha(k, k + 1) - \epsilon(k)
\end{equation}
for $k \in \{1, \ldots, N - 1\}$. An equivalent definition is
\begin{equation}
\alpha \cdot \sigma = (\alpha + \delta) \sigma - \delta
\end{equation}
where $\delta = (N - 1, \ldots, 1, 0)$, as in (3.2) in §3. Since $\alpha \cdot \sigma$ has $i$th entry equal to $(\alpha + \delta)_{i\sigma^{-1}} - \delta_i = a_{i\sigma^{-1}} + (N - i\sigma^{-1}) - (N - i)$, it follows that
\begin{equation}
(\alpha \cdot \sigma)_i = a_{i\sigma^{-1}} - i\sigma^{-1} + i.
\end{equation}

Definition 4.5. For $\alpha$ a composition with $\ell(\alpha) \leq N$ and $\sigma \in \text{Sym}_N$ we define $\alpha \cdot \sigma$ to be the integer sequence obtained from $(a_1, \ldots, a_N) \cdot \sigma$ by appending zeros.

Note that $\alpha \cdot \sigma$ may have negative parts, so is not in general a composition. By Question 22, if $\lambda$ is a partition with $\ell(\lambda) \leq N$ and $\sigma \in \text{Sym}_N$, then $\lambda \cdot \sigma$ is a partition if and only if $\sigma = \text{id}_{\text{Sym}_N}$. Note that, by Lemma 4.4, if $t \in \text{SSYT}(\mu, \alpha)$ and $E_k(t)$ is defined then
\begin{equation}
S_k E_k(t) \in \text{SSYT}(\mu, \alpha \cdot (k, k + 1)).
\end{equation}

Lemma 4.9 below gives a close connection between the dot action and the Jacobi–Trudi Identity. See MathOverflow 80150 for some other appearances of the dot action.

4.4. Latticed tableaux and the $J$ involution. Say that a word $w$ is latticed if it has no $k$-unpaired $(k + 1)s$, for any $k$. Equivalently, by Definition 4.1, for each $k$, when $w$ is read from right to left, the number of $ks$ is always equal or greater than the number of $(k + 1)s$, for every $k$. If $w$ is not latticed and the rightmost $j$-unpaired $j + 1$ in $w$ is a $k + 1$, say that $w$ is $k$-unlatticed. (This term is not standard but is temporarily useful.) We extend these definitions to tableaux using the word map.
**Definition 4.6.** Let $\lambda$ be a partition of $n$ with $\ell(\lambda) \leq N$. Let $\mu$ be a partition of $n$. Let

$$\mathcal{T} = \bigcup_{\sigma \in \text{Sym}_N} \text{SSYT}(\mu, \lambda \cdot \sigma).$$

(If $\lambda \cdot \sigma$ has a negative part then take $\text{SSYT}(\mu, \lambda \cdot \sigma) = \emptyset$.) Define $J : \mathcal{T} \to \mathcal{T}$ by $J(t) = t$ if $t$ is latticed and $J(t) = S_k E_k(t)$ if $t$ is $k$-unlatticed.

**Lemma 4.7.** Take notation as in Definition 4.6. The map $J$ is an involution on $\mathcal{T}$. Let $t \in \text{SSYT}(\mu, \lambda \cdot \sigma)$.

(i) If $t$ is $k$-unlatticed then $J(t) \in \text{SSYT}(\mu, \lambda \cdot (\sigma(k, k+1)))$.

(ii) If $t$ is latticed then $\sigma = \text{id}_{\text{Sym}_N}$, $\lambda = \mu$ and $t$ is the unique element of $\text{SSYT}(\lambda, \lambda)$.

**Proof.** Let $t \in \text{SSYT}(\mu, \lambda \cdot \sigma)$ be $k$-unlatticed. The words $w(t)$ and $w(J(t))$ differ only in the positions of the $k$-unpaired entries of $w(t)$. If the $k$-unpaired subword of $w(t)$ is $k^a(k+1)^b$ then the $k$-unpaired subword of $w(J(t))$ is $k^{a-1}(k+1)^{b+1}$. Let the rightmost $k+1$ in $w(t)$ be in position $i$. Recall that, by Definition 4.1, a $j+1$ is $j$-unpaired in a word $v$ if and only if it sets a new record for the excess of $(j+1)$'s over $j$s when $v$ is read right to left. Since positions $i+1, \ldots, n$ of $w(t)$ and $w(J(t))$ are equal, it follows that the subword in these positions is latticed in both $w(t)$ and $w(J(t))$. Since $w(J(t))_i = k+1$, we see that $w(J(t))$ is $k$-unlatticed. Hence $J(J(t)) = S_k E_k(J(t))$. It now follows from Lemma 4.4 that $J(J(t)) = t$. Hence $J$ is an involution.

Part (i) follows from (4.3). For (ii), if $J(t) = t$ then the content of $t$ is a partition, so $t \in \text{SSYT}(\mu, \lambda)$ by Question 22. Considering each row of $t$ in turn, starting with the first row, we see that the lattice condition implies that $\mu = \lambda$ and all the entries in row $i$ of $t$ equal to $i$, for each $i \in \{1, \ldots, \ell(\lambda)\}$. \hfill $\square$

Note that (ii) shows that $J$ has a unique fixed point in $\mathcal{T}$. When the definition of $J$ is extended to skew-tableaux there may be many fixed points: see Question 30.

**Example 4.8.** Take $\lambda = (5, 3, 1)$. The orbit of $(5, 3, 1)$ under the dot action can be computed by repeatedly applying the transpositions $(1, 2)$ and $(2, 3)$ using (4.1).

\[
\begin{array}{c}
(5, 3, 1) \\
\downarrow (1, 2) \\
(2, 3) \\
\downarrow (1, 2) \\
(5, 0, 4) \\
\downarrow (1, 2) \\
(-1, 3, 7)
\end{array}
\]

In fact, by the first part of Question 22, there is no need to carry on once a negative entry appears, but it is maybe interesting to see the braid relation $(1, 2)(2, 3)(1, 2) = (2, 3)(1, 2)(2, 3)$ appearing.
The four compositions \((5, 3, 1), (2, 6, 1), (5, 0, 4)\) and \((2, 0, 7)\) correspond to the four non-zero summands in the Jacobi–Trudi Identity for \(s_{(5,3,1)}\). We have
\[
a_\delta ev_3 s_{(5,3,1)} = a_\delta ev_3 h_{(5,3,1)} - a_\delta ev_3 h_{(2,6,1)} - a_\delta ev_3 h_{(5,0,4)} + a_\delta ev_3 h_{(2,0,7)}
= \sum_\mu (|SSYT(\mu, (5,3,1))| - |SSYT(\mu, (2,6,1))| - |SSYT(\mu, (5,0,4))| + |SSYT(\mu, (2,0,7))|) a_{\delta + \mu}
\]
where the second line follows from Young’s Rule (Theorem 3.8) for antisymmetric polynomials. Applying the \(f\) involution we see that the coefficient of \(ev_3 a_{\delta + \mu}\) is the number of latticed semistandard Young tableaux of shape \(\mu\) and content \((5,3,1)\). As remarked above, if \(\mu = (5,3,1)\) there is a unique such tableau, namely
\[
\begin{array}{cccc}
1 & 1 & 1 & 1 \\
2 & 2 & 2 \\
3 & & & \\
\end{array}
\]
and otherwise there are none. Hence \(a_\delta s_{(5,3,1)}(x_1, x_2, x_3) = a_{\delta + (5,3,1)}\) and \(s_{(5,3,1)}(x_1, x_2, x_3) = a_{\delta + (5,3,1)} / a_\delta\).

Two explicit examples of the \(f\) involution are given below.

(i) Take \(\mu = (5,3,1)\). Since \(\mu\) does not dominate \(P(2,6,1) = (6,2,1)\), \(P(5,0,4) = (5,4)\) or \(P(2,0,7) = (7,2)\), the set \(\mathcal{T}\) in Definition 4.6 is simply \(SSYT((5,3,1), (5,3,1))\), and its unique element is the fixed point of \(f\) shown above.

(ii) Take \(\mu = (6,3)\). Then
\[
\mathcal{T} = SSYT((6,3), (5,3,1)) \cup SSYT((6,3), (2,6,1)) \cup SSYT((6,3), (5,0,4))
= \{1 1 1 1 1 2, 1 1 1 1 1 3, 2 2 2, 2 2 3\} \cup \{1 1 2 2 2 2, 2 2 3\} \cup \{1 1 1 1 1 1 3, 3 3 3\}
\]
Label the tableaux \(t_1, t_2, t_3, t_4\) from left to right. We have \(f(t_1) = S_1 E_1(t_1) = t_3\) and \(f(t_2) = S_2 E_2(t_2) = t_4\). Of course this implies that \(f(t_3) = t_1\) and \(f(t_4) = t_2\).

4.5. **Equivalence of definitions of Schur functions.** The previous example shows the main ideas required. We need the following version of the Jacobi–Trudi Identity (Theorem 2.1).

**Lemma 4.9.** Let \(\lambda\) be a partition of \(n\) with \(\ell(\lambda) \leq N\). Then
\[
s_\lambda = \sum_{\sigma \in \text{Sym}_n} h_{\lambda, \sigma} \text{sgn}(\sigma).
\]

**Proof.** The Jacobi–Trudi Identity states that if \(\ell(\lambda) \leq M\) then
\[
s_\lambda = \det(h_{\lambda, \sigma})_{1 \leq i, j \leq M}.
\]
Take $M = N$. For each $\tau \in \text{Sym}_N$, the summand of the determinant given by taking $h_{\lambda_i-\tau}$ from row $i$ of the matrix, for each $i \in \{1, \ldots, N\}$, is $\text{sgn}(\tau) \prod_{i=1}^{N} h_{\lambda_i-\tau}$. Therefore
\[
s_{\lambda} = \sum_{\tau \in \text{Sym}_N} \text{sgn}(\tau) \prod_{i=1}^{N} h_{\lambda_i-\tau} = \sum_{\sigma \in \text{Sym}_N} \text{sgn}(\sigma) \prod_{i=1}^{N} h_{\lambda_{i-1}-\sigma^{-1}+i} = \sum_{\sigma \in \text{Sym}_N} \text{sgn}(\sigma) h_{\lambda,\sigma}
\]
where the final equality follows immediately from (4.2).

In the path model used to prove Theorem 2.1, path tuples for which the final destination of the path starting at $(M-i,1)$ is $(\lambda_{\tau} + M - \tau, N)$ correspond to the summand $\text{sgn}(\tau) \prod_{i=1}^{M} h_{\lambda_{\tau} - i\tau + i}$ in the expansion of the determinant. (Since the path starting at $(M-i,1)$ makes $\lambda_{\tau} - i\tau + i$ right steps.) Swapping the final destinations of the paths starting at $(M-i,1)$ and $(M-j,1)$ replaces the terms $h_{\lambda_{\tau} + i\tau - i}$ and $h_{\lambda_{\tau} + j\tau - j}$ in this product with $h_{\lambda_{\tau} + i\tau}$ and $h_{\lambda_{\tau} + j\tau}$, respectively. Thus $\tau$ is replaced with $(i, j)\tau$.

**Theorem 4.10.** Let $\lambda$ be a partition of $n$ with $\ell(\lambda) \leq N$. Then $s_{\lambda}(x_1, \ldots, x_N) = a_{\lambda+\delta}/a_\delta$.

**Proof.** By Lemma 4.9 we have
\[
a_\delta s_{\lambda}(x_1, \ldots, x_N) = \sum_{\sigma \in \text{Sym}_N} a_\delta h_{\lambda,\sigma}(x_1, \ldots, x_N) \text{sgn}(\sigma).
\]
By Young’s rule (as stated in Corollary 3.9) we have $h_{\lambda,\sigma}(x_1, \ldots, x_N) = \sum_{\mu \vdash n} \text{SSYT}(\mu, \lambda \cdot \sigma) a_{\mu+\delta}/a_\delta$. (Recall that the results in §3 apply to the antisymmetric Schur polynomials defined by $a_{\delta+\mu}/a_\delta$.) Therefore
\[
a_\delta s_{\lambda}(x_1, \ldots, x_N) = \sum_{\mu \vdash n} c_{\mu} a_{\delta+\mu}
\]
where
\[
c_{\mu} = \sum_{\sigma \in \text{Sym}_N} |\text{SSYT}(\mu, \lambda \cdot \sigma)| \text{sgn}(\sigma).
\]
Fix $\mu$. Let $T = \bigcup_{\sigma \in \text{Sym}_N} \text{SSYT}(\mu, \lambda \cdot \sigma)$ and let $J : T \to T$ be as defined in Definition 4.6. By Lemma 4.7, if $t \in \text{SSYT}(\mu, \lambda \cdot \sigma)$ and $J(t) \neq t$ then $J(t) \in \text{SSYT}(\mu, \lambda \cdot \sigma(k, k+1))$ for some $k \in \{1, \ldots, N-1\}$. Applying $J$ therefore cancels all contributions to $c_{\mu}$ except those coming from tableaux $t \in T$ such that $J(t) = t$. By Lemma 4.7, the unique fixed point of $J$ on $T$ is the unique element of $\text{SSYT}(\lambda, \lambda)$. Therefore $c_{\mu} = 0$ unless $\mu = \lambda$ and $c_{\lambda} = 1$. Hence $a_\delta s_{\lambda}(x_1, \ldots, x_N) = a_{\delta+\lambda}$, as required. \[\square\]
4.6. Results for Schur functions. Using (1.4) in §1.6 it is now routine to translate all the results in §3 to results on Schur functions. Let \( \lambda \) be a partition of \( n \) and let \( r \in \mathbb{N}_0 \). Dividing through by \( a_\delta \) in Pieri’s Rule (Theorem 3.7) we get

\[
s_\lambda(x_1, \ldots, x_N)e_r(x_1, \ldots, x_N) = \sum_{\mu \in P_r(\lambda) \atop \ell(\mu) \leq N} s_\mu(x_1, \ldots, x_N)
\]

for all \( N \in \mathbb{N} \) such that \( \ell(\lambda) \leq N \). Provided \( N \geq r + n \) the condition \( \ell(\mu) \leq N \) always holds, so we have

\[
ev_N(s_\lambda e_r) = \sum_{\mu \in P_r(\lambda)} \ev_N(s_\mu)
\]

for all \( N \) sufficiently large. Hence, by (1.4), \( s_\lambda e_r = \sum_{\mu \in P_r(\lambda)} s_\mu \). Young’s Rule and the Murnaghan Nakayama Rule for Schur functions follow in the same way.

5. Inner product on \( \Lambda \)

Define an inner product \( \langle \ , \ \rangle : \Lambda \times \Lambda \to \mathbb{C} \) by extension of

\[
\langle s_\lambda, s_\mu \rangle = \begin{cases} 1 & \text{if } \lambda = \mu \\ 0 & \text{otherwise.} \end{cases}
\]

5.1. Dual bases. If \( \{ f_\mu : \mu \vdash n \} \) and \( \{ g_\nu : \nu \vdash n \} \) are bases of \( \Lambda_n \) such that

\[
\langle f_\mu, g_\nu \rangle = \begin{cases} 1 & \text{if } \mu = \nu \\ 0 & \text{otherwise.} \end{cases}
\]

then we say \( \{ f_\mu : \mu \vdash n \} \) and \( \{ g_\nu : \nu \vdash n \} \) are dual bases. Thus \( \{ s_\mu : \mu \vdash n \} \) is a self-dual orthonormal basis of \( \Lambda_n \).

The following lemma gives an efficient way to prove duality relationships between the symmetric functions we have studied.

**Lemma 5.1.** Suppose that \( \{ f_\mu : \mu \vdash n \} \) and \( \{ g_\nu : \nu \vdash n \} \) are bases of \( \Lambda_n \) such that

\[
f = \sum_{\nu \vdash n} \langle f, g_\nu \rangle f_\nu
\]

for all \( f \in \Lambda_n \). Then \( \{ f_\mu : \mu \vdash n \} \) and \( \{ g_\nu : \nu \vdash n \} \) are dual bases.

**Proof.** Taking \( f = f_\mu \) we get \( f_\mu = \sum_{\nu \vdash n} \langle f_\mu, g_\nu \rangle f_\nu \). The result follows by comparing coefficients. \( \square \)

**Theorem 5.2.** The bases \( \{ \text{mon}_\nu : \nu \vdash n \} \) and \( \{ h_\mu : \mu \vdash n \} \) of \( \Lambda_n \) are dual.

**Proof.** By the combinatorial definition of \( s_\lambda \) we have

\[
s_\lambda = \sum_{\nu \vdash n} |\text{SSYT}(\lambda, \nu)| \text{mon}_\nu.
\]
By Young’s rule (as stated in Corollary 3.9 in the antisymmetric setting), we have
\[ h_v = \sum_{\lambda \vdash n} |SSYT(\lambda, v)| s_\lambda. \]

Hence \( \langle s_\lambda, h_v \rangle = |SSYT(\lambda, v)| \). Substituting in the first equation we get
\[ s_\lambda = \sum_{\nu \vdash n} \langle s_\lambda, h_v \rangle \text{mon}_\nu. \]
Hence \( f = \sum_{\nu \vdash n} \langle f, h_v \rangle \text{mon}_\nu \) for all \( f \in \Lambda_n \).

Now apply Lemma 5.1.

The analogous result for power sum symmetric functions can also be obtained by this method, but the proof is a little technical. See Proposition 7.9.3 in [14] for a shorter, and more usual, alternative proof, using Cauchy’s Identity
\[ \prod_{i=1}^{\infty} \frac{1}{1-x_i y_j} = \exp \left( \sum_{n=1}^{\infty} \frac{p_n(x)p_n(y)}{n} \right). \]

It is helpful to use a definition from the character theory of the symmetric group. Given a partition \( \mu \) of \( n \) with \( \ell(\mu) = k \), and \( a \) a composition of \( n \), let \( \sigma_a \in \text{Sym}_n \) be a permutation of cycle-type \( a \) and let \( \pi^\mu(a) \) be the number of ordered set partitions \( (P_1, \ldots, P_k) \) such that each \( P_i \) is a union of orbits of \( \sigma_a \). Thus \( \pi^\mu \) is the permutation character of \( \text{Sym}_n \), acting on the cosets of the Young subgroup \( \text{Sym}_\mu = \text{Sym}_{\mu_1} \times \cdots \times \text{Sym}_{\mu_r} \).

For example, take \( r \leq n/2 \). Then \( \pi^{(n-r,r)}(\sigma) \) is the number of \( r \)-subsets of \( \{1, \ldots, n\} \) fixed by \( \sigma \).

**Theorem 5.3.** The bases \( \{ p_\mu : \mu \vdash n \} \) and \( \{ \Pi^\nu_{\pi^\nu} : \nu \vdash n \} \) of \( \Lambda_n \) are dual.

**Proof.** Fix a partition \( \mu \) of \( n \) with \( \ell(\mu) = k \). Given a composition \( a \) of \( n \), having exactly \( a_j \) parts of size \( j \) for each \( j \in \{1, \ldots, n\} \), define an \( a \)-packing matrix to be an \( k \times n \) matrix \( C \) such that \( \sum_{j=1}^{n} j C_{ij} = a_j \) for each \( i \in \{1, \ldots, k\} \) and \( \sum_{i=1}^{k} C_{ij} = a_j \) for each \( j \in \{1, \ldots, n\} \).

**Claim 1:**
\[ \pi^\mu(a) = \prod_{j=1}^{n} \frac{a_j!}{C_{1j}! \cdots C_{kj}!} \]
where the sum is over all packing matrices \( C \). **Proof:** put \( C_{ij} \) of the \( a_j \) orbits of \( \sigma_a \) of size \( j \) in \( P_i \). There are \( \binom{C_{1j} \cdots C_{kj}}{a_j} \) ways to choose which \( a_j \) orbits of size \( j \) go into each of \( P_1, \ldots, P_k \).

**Claim 2:**
\[ p_\gamma = \sum_{\mu \vdash n} \pi^\mu(a) \text{mon}_\mu. \]

**Proof:** suppose that when we multiply out
\[ p_1^{a_1} p_2^{a_2} \cdots p_n^{a_n} = (x_1 + \cdots + x_N)^{a_1} (x_1 + \cdots + x_N)^{a_2} \cdots (x_1^n + \cdots + x_N^n)^{a_n} \]
we choose to take \( x^j \) from exactly \( C_{ij} \) of the \( a_j \) terms in the product \((x_1^1 + \cdots + x_N)^{a_j}\). We can do this in \( (C_{ij}, \ldots, C_{k^j}) \) ways, for each \( j \in \{1, \ldots, n\} \). Moreover, the product is \( x^\mu \) if and only if \( C \) is an \( \alpha \)-packing matrix. Claim 1 now implies that the coefficient of \( \text{mon}_\mu \) is \( \pi^\mu(\alpha) \).

Claim 3:
\[
h_\tau = \sum_{\beta \vdash \tau} \frac{p_\beta}{z_\beta}
\]

Proof: This follows from the Cycle Index Formula (Theorem 1.11) and the following remark.

Claim 4:
\[
h_\mu = \sum_{a \vdash n} \frac{p_a}{z_a} \pi^\mu(\alpha).
\]

Proof: This follows by multiplying out the product \( h_{\mu_1} \ldots h_{\mu_k} \), using Claim 3. The argument is similar to Claim 2, and is left as an exercise: see Question 26. \( \Box \)

By Claim 2 we have
\[
\langle h_\mu, p_\nu \rangle = \pi^\mu(\nu).
\]

Substituting in Claim 4 we get
\[
h_\mu = \sum_{\nu \vdash n} \langle h_\mu, p_\nu \rangle \frac{p_\nu}{z_\nu}.
\]

Therefore \( f = \sum_{\nu \vdash n} \langle f, p_\nu \rangle \frac{p_\nu}{z_\nu} \) for all \( f \in \Lambda_n \) and the result follows from Lemma 5.1. \( \Box \)

5.2. Gale–Ryser revisited. By Question 25 we have
\[
h_\mu = \sum_{\lambda \vdash n} |\text{SSYT}(\lambda, \mu)| s_\lambda
\]
\[
e_\nu = \sum_{\lambda \vdash n} |\text{SSYT}(\lambda', \nu)| s_\lambda
\]

Hence
\[
\langle h_\mu, e_\nu \rangle = \sum_{\lambda \vdash n, \lambda' \vdash \nu} |\text{SSYT}(\lambda, \mu)||\text{SSYT}(\lambda', \nu)|.
\]

We saw in Lemma 1.2 that \( e_\nu = \sum_{\mu \vdash n} N_{\mu \nu} \text{mon}_\mu \). Taking the inner product with \( h_\mu \) we obtain \( \langle h_\mu, e_\nu \rangle = N_{\mu \nu} \). Therefore, to show that if \( \nu' \vdash \mu \) then \( N_{\mu \nu} > 0 \) it is sufficient to prove the following (related) result on Kostka Numbers. The proof is the symmetric functions version of Theorem 2.2.20 in [5].

Lemma 5.4. If \( \lambda \vdash \mu \) then \( |\text{SSYT}(\lambda, \mu)| \geq 1 \).
Proof. Obviously $K_{\lambda\mu} = 1$. Let $\mu$ and $\mu^*$ be neighbours in the dominance order, with $\mu \gg \mu^*$, so by Question 2, $\mu_i^* = \mu_i - 1$, $\mu_j^* = \mu_j + 1$ for some $i < j$, and $\mu_k^* = \mu_k$ if $k \neq i, j$. Since $h_{(a,b)} = h_{(a+1,b-1)} + s_{(a,b)}$ whenever $a \geq b$, by Corollary 2.4, we have

\[
K_{\lambda\mu} = \prod_{k \neq i, j} h_{\mu_k} h_{\mu_i - 1} h_{\mu_j + 1} = \prod_{k \neq i, j} h_{\mu_k} (h_{\mu_i} h_{\mu_j} + s_{(\mu_i - 1, \mu_j + 1)})
\]

and so if $f = \prod_{k \neq i, j} h_{\mu_k}$ then

\[
K_{\lambda\mu^*} = \langle s_{\lambda}, h_{\mu^*} \rangle = \langle s_{\lambda}, h_{\mu} \rangle + \langle s_{\lambda}, f s_{(\mu_i - 1, \mu_j + 1)} \rangle = K_{\lambda\mu} + \langle s_{\lambda}, f s_{(\mu_i - 1, \mu_j + 1)} \rangle \geq K_{\lambda\mu}.
\]

The lemma follows. □

This gives the direction of the Gale–Ryser Theorem not proved in §1.2. The notes for Question 11 give references for combinatorial proofs of Lemma 5.4.

5.3. The $\omega$ involution. The following definition is maybe best motivated by the connection with characters of the symmetric group, where it corresponds to multiplication by the sign character: see §5.5.

Definition 5.5. Let $\omega : \Lambda \to \Lambda$ be the ring homomorphism defined by $\omega(e_n) = e_n$.

It follows fairly easily from Newton’s Identity (1.2) that $\omega(e_n) = h_n$; see Question 10. Thus $\omega$ is an involution. The related identities in (1.6) or Question 3(f) can be used to show that $\omega(p_n) = (-1)^{n-1} p_n$. (Again see Question 10.) Hence

\[
(5.4) \quad \omega(p_{\lambda}) = \mathrm{sgn}(\sigma_{\lambda}) p_{\lambda}
\]

where $\sigma_{\lambda}$ is a permutation of cycle-type $\lambda$.

Lemma 5.6. Let $\lambda$ be a partition. Then $\omega(s_{\lambda}) = s_{\lambda'}$.

Proof. Comparing (5.2) and (5.3) we get

\[
\sum_{\lambda \vdash n} |\text{SSYT}(\lambda, \mu)| \omega(s_{\lambda}) = \sum_{\lambda' \vdash n} |\text{SSYT}(\lambda', \mu)| s_{\lambda}.
\]

Suppose inductively that $\omega(s_{\lambda}) = s_{\lambda'}$ if $\lambda \supseteq \mu$. (The base case is $\lambda = (n)$, when we have $\omega(s_{(n)}) = \omega(h_n) = e_n = s_{(1^n)}$.) Let $\mu$ be a neighbour of $\mu$ in the dominance order with $\mu \gg \mu^*$. The previous equation implies
that
\[
\sum_{\lambda \vdash n, \mu \geq \mu} |\text{SSYT}(\lambda, \mu^*)| \omega(s_\lambda) + |\text{SSYT}(\mu^*, \mu^*)| \omega(s_{\mu^*}) = \sum_{\lambda' \vdash n, \lambda' \geq \mu} |\text{SSYT}(\lambda', \mu^*)| s_\lambda + |\text{SSYT}(\mu^*, \mu^*)| s_{\mu'}.
\]
By induction we have \(|\text{SSYT}(\lambda, \mu^*)| \omega(s_\lambda) = |\text{SSYT}(\lambda, \mu^*)| s_{\lambda'} \) for \(\lambda \geq \mu\), hence the sums on each side agree. Therefore \(\omega(s_{\mu^*}) = s_{\mu'}\) as required for the inductive step. \(\Box\)

**Alternative proof.** By the Murnaghan–Nakayama rule we have
\[
p_\mu = \sum_{\lambda' \vdash n} c^\lambda(\mu) s_\lambda
\]
where \(c^\lambda(\mu)\) is the weighted sum of the signs of border-strip tableaux of shape \(\lambda\) and type \(\mu\). Taking the inner product with \(s_\lambda\) we get
\[
\langle s_\lambda, p_\mu \rangle = c^\lambda(\mu).
\]
Hence
\[
s_\lambda = \sum_{\mu' \vdash n} \langle s_\lambda, p_\mu \rangle \frac{p_\mu}{z_\mu} = \sum_{\mu' \vdash n} c^\lambda(\mu) \frac{p_\mu}{z_\mu}.
\]
Applying \(\omega\) we obtain
\[
\omega(s_\lambda) = \sum_{\mu' \vdash n} c^\lambda(\mu) \operatorname{sgn}(\sigma_\mu) \frac{p_\mu}{z_\mu} = \sum_{\mu' \vdash n} c^\lambda(\mu) \frac{p_\mu}{z_\mu} = s_{\lambda'}
\]
where \(\sigma_\mu \in \text{Sym}_n\) is a permutation of cycle-type \(\mu\). Here the middle equality is proved by transposing the border-strip tableaux counted (with signs) in \(c^\lambda(\mu)\). \(\Box\)

5.4. **Littlewood–Richardson Rule.** In the final lecture I sketched a proof of the Littlewood–Richardson Rule. This needs some extensions to the results proved above, specifically the Jacobi–Trudi formula for Schur functions labelled by skew-partitions, and the Lascoux–Schützenberger involution for skew-tableaux. Essentially the proof is the specialization of the proof of the SXP rule in [18] (in turn inspired by [12]), replacing multitableaux with skew-tableaux. See Question 27, 30, and 31 and the outline answers.

5.5. **Connection with the symmetric group.** Let \(n \in \mathbb{N}\). Let \(\text{Cl}(\text{Sym}_n)\) be the set of functions \(\text{Sym}_n \to \mathbb{C}\) that are constant on conjugacy classes. Thus \(\text{Cl}(\text{Sym}_n)\) has as a basis the indicator functions \(1_\alpha\) for \(\alpha\) a partition of \(n\) defined by
\[
1_\alpha(\sigma) = \begin{cases} 1 & \text{if } \sigma \text{ has cycle type } \alpha \\ 0 & \text{otherwise}. \end{cases}
\]
The elements of \( \text{Cl}(\text{Sym}_n) \) are called class functions. There is an inner product on \( \text{Cl}(\text{Sym}_n) \) defined by

\[
\langle \phi, \psi \rangle = \frac{1}{n!} \sum_{\sigma \in \text{Sym}_n} \phi(\sigma) \overline{\psi(\sigma)}.
\]

**Proposition 5.7.** There is a linear isometry \( \Lambda_n \to \text{Cl}(\text{Sym}_n) \) defined by \( p_\alpha z_\alpha \mapsto 1_\alpha \) for each \( \alpha \vdash n \). Under this isometry the \( \omega \)-involution corresponds to multiplication by the sign character and the image of \( s_\lambda \) is an irreducible character of \( \text{Sym}_n \).

**Proof.** By Claim 4 in the proof of Theorem 5.3 we have \( h_\mu = \sum_{\alpha \vdash n} \frac{p_\alpha}{z_\alpha} \pi^\mu(\alpha) \). Therefore the image of \( h_\mu \) is the permutation character \( \pi^\mu \). Since \( \langle h_\mu, p_\alpha z_\alpha \rangle = \frac{\pi^\mu(\alpha)}{z_\alpha} = \langle \pi^\mu, 1_\alpha \rangle \), the map is an isometric embedding. Since \( \Lambda_n \) and \( \text{Cl}(\text{Sym}_n) \) both have dimension equal to the number of partitions of \( n \), it is an isometry.

Applying the \( \omega \)-involution to Claim 4 and using (5.4) we get \( e_\mu = \sum_{\alpha \vdash n} \frac{p_\alpha}{z_\alpha} \pi^\mu(\alpha) \sgn(\sigma_\alpha) \), where \( \sigma_\alpha \) is an element of cycle type \( \alpha \). Therefore the image of \( e_\mu \) is \( \pi^\mu \sgn_{\text{Sym}_n} \), where \( \sgn_{\text{Sym}_n} \) is the sign character of \( \text{Sym}_n \). This proves the second claim.

By (5.2) and (5.3) we have \( h_\mu = h + s_\mu \) and \( e_\mu' = e + s_\mu \) where \( h \) is a sum of Schur functions \( s_\lambda \) for \( \lambda \supseteq \mu \) and \( e \) is a sum of Schur functions \( s_\lambda \) for \( \lambda \subsetneq \mu \). Therefore \( \langle h_\mu, e_\mu' \rangle = 1 \) and so the ordinary characters \( \pi^\mu \) and \( \pi^\mu' \sgn \) have a unique irreducible constituent in common, namely the image of \( s_\lambda \).

Given a partition \( \lambda \) of \( n \), let \( \chi^\lambda \in \text{Cl}(\text{Sym}_n) \) denote the image of \( s_\lambda \). By Corollary 3.13, taking the inner product of each side with \( s_\lambda \), we have

\[
\langle s_\lambda, p_\alpha \rangle = c^\lambda(\alpha)
\]

where \( c^\lambda(\alpha) \) is the signed sum of border-strip tableaux of shape \( \lambda \) and content \( \alpha \) defined in Definition 3.12. Hence \( c^\lambda(\alpha) = \langle \chi^\lambda, z_\alpha 1_\alpha \rangle = \chi^\lambda(\sigma_\alpha) \) where \( \sigma_\alpha \) has cycle type \( \alpha \). The Murnaghan–Nakayama rule therefore gives the values of \( \chi^\lambda \), as claimed after Corollary 3.13.

In fact it is more common to work with the inverse map, known as the characteristic isomorphism, defined for \( \phi \in \text{Cl}(\text{Sym}_n) \) by

\[
(5.5) \quad \phi \mapsto \frac{1}{n!} \sum_{\sigma \in \text{Sym}_n} \phi(\sigma) p_{\rho(\sigma)}
\]

where \( \rho(\sigma) \) is the cycle-type of \( \sigma \in \text{Sym}_n \). Let \( \chi : \Lambda \to \bigoplus_{n \in \mathbb{N}_0} \text{Cl}(\text{Sym}_n) \) be the resulting isometry. (We define the inner product of two class functions of symmetric groups of different degree to be zero.) The right-hand side is then a graded ring with product

\[
\phi \circ \psi = (\phi \times \psi)^{\text{Sym}_{m+n}}_{\text{Sym}_m \times \text{Sym}_n}
\]
where $\phi \in \text{Cl}(\text{Sym}_n)$ and $\psi \in \text{Cl}(\text{Sym}_n)$ and the arrow denotes induction. We have already proved most of the following remarkable theorem. In it, recall from §5.1 that $\pi^\mu$ is the permutation character of Sym$_n$ acting on the cosets of the Young subgroup Sym$_\mu$.

**Theorem 5.8.** The map $\text{ch} : \bigoplus_{n \in \mathbb{N}_0} \text{Cl}(\text{Sym}_n) \to \Lambda$ is an isometric ring isomorphism. It satisfies $\text{ch}(\chi^\lambda) = s_\lambda$, $\text{ch}(\pi^\mu) = h_\mu$, $\text{ch}(1^\alpha) = p_\alpha z^\alpha$ for all partitions $\lambda, \mu, \alpha$. Moreover $\text{ch}(\phi \text{sgn}_{\text{Sym}_n}) = \omega(\phi)$ for all class functions $\phi$ of Sym$_n$.

**Proof.** It only remains to show that $\text{ch}$ is a ring homomorphism. Let $\lambda$ and $\mu$ be partitions of $n$. We have $\pi^\lambda \circ \pi^\mu = \pi^\nu$ where $\nu$ is the partition whose multiset of parts is the union of the multisets of parts of $\lambda$ and $\mu$. Therefore

$$\text{ch}(\pi^\lambda \pi^\mu) = \text{ch}(\pi^\nu) = h_\nu = h_\lambda h_\nu = (\text{ch}(\pi^\lambda))(\text{ch}(\pi^\mu))$$

as required. \qed

**Remark 5.9.** Suppose we fix $N \in \mathbb{N}$ and attempt to define $C[x_1, \ldots, x_N]_{\text{Sym}_N} \to \bigoplus \text{Cl}(\text{Sym}_n)$ by $s_\lambda(x_1, \ldots, x_N) \to \chi^\lambda$. There is an immediate problem: this map is not well-defined because the $s_\lambda(x_1, \ldots, x_N)$ are not linearly independent when $N < \ell(\lambda)$. (Indeed, by Lemma 1.15, we have $s_{(1^n)}(x_1, \ldots, x_N) = 0$ whenever $N < n$.) This shows that working with infinitely many variables, i.e. symmetric functions rather than symmetric polynomials, is essential to get a nice correspondence with the symmetric group.

The corollary below follows from the Littlewood–Richardson rule (in a more explicit form), but has a much simpler proof using character theory.

**Corollary 5.10.** Let $\mu \vdash m$ and $\nu \vdash n$. Then $s_\mu s_\nu$ is a non-negative integral linear combination of Schur functions.

**Proof.** The corresponding claim for symmetric group characters, that $(\chi_\mu \times \chi_\nu)^{\text{Sym}_{m+n}}_{\text{Sym}_m \times \text{Sym}_n}$ is a non-negative integral linear combination of irreducible characters, is obvious. \qed

### 5.6. The cycle index revisited

Given $\sigma \in S_n$, let

$$\text{cyctype}(\sigma) = (1^{\text{cy}_1(\sigma)}, \ldots, n^{\text{cy}_n(\sigma)})$$

be the cycle type of $\sigma$. Let $G \leq \text{Sym}_n$ be a permutation group. The cycle index of $G$ is defined by

$$\text{cyc}_G = \frac{1}{|G|} \sum_{g \in G} p_{\text{cyctype}(g)}.$$
The general cycle index just defined appears in a beautiful theorem of Polya, stated in §5.7 below and proved using the characteristic isometry. Here we give some more immediate motivation for the cycle index using the results from §1.11.

An explicit definition of the inverse of the characteristic isometry will be useful. For each partition $\lambda$ of $n$, let $\sigma_\lambda \in \text{Sym}_n$ be a chosen element such that $\text{cyctype}(\sigma_\lambda) = \lambda$. Then $\text{ch}^{-1}: \Lambda_n \to \text{Cl}(\text{Sym}_n)$ is the map

$$\text{ch}^{-1} \left( \sum_\lambda a_\lambda \frac{p_\lambda}{z_\lambda} \right) = \phi$$

where $\phi \in \text{Cl}(\text{Sym}_n)$ is defined by $\phi(\sigma_\lambda) = a_\lambda$.

**Example 5.11.**

(1) Since $\text{Sym}_n$ has $n!/z_\lambda$ elements of cycle type $\lambda$, $\text{cyc}_{\text{Sym}_n} = \sum_\lambda p_\lambda z_\lambda$. Here $\text{cyc}_{\text{Sym}_n}$ is the trivial character of $\text{Sym}_n$. By the remark following Theorem 1.11, $\text{cyc}_{\text{Sym}_n} = h_n$. Moreover, by (1.8), $\exp \sum_{k=1}^{\infty} \frac{p_k}{k} t^k = \sum_{n=0}^{\infty} \text{cyc}_{\text{Sym}_n} t^n$. We saw in §1.11 some of the applications of the cycle index of $\text{Sym}_n$ to enumerating permutations.

(2) $\text{cyc}_1 = p_1^n$ and $\text{ch}^{-1} p_1^n = n! \mathbb{1}_{(1^n)}$ is the regular character of $\text{Sym}_n$; this is the permutation character of $\text{Sym}_n$ acting on itself by right multiplication.

(3) Let $H = \langle (1, 2, 3, 4) \rangle$ and let $G = \langle (1, 2, 3, 4), (1, 3) \rangle$ be the dihedral group. Then

- $\text{cyc}_H = \frac{1}{4} (p_{(1,1,1,1)} + p_{(2,2)} + 2p_{(4)})$
- $\text{cyc}_G = \frac{1}{8} (p_{(1,1,1,1)} + 2p_{(2,1,1)} + 3p_{(2,2)} + 2p_{(4)})$

and the corresponding class functions on $\text{Sym}_4$ are

<table>
<thead>
<tr>
<th></th>
<th>(1, 1, 1, 1)</th>
<th>(2, 1, 1)</th>
<th>(2, 2)</th>
<th>(3, 1)</th>
<th>(4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{ch}^{-1} \text{cyc}_H$</td>
<td>6</td>
<td>0</td>
<td>2</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>$\text{ch}^{-1} \text{cyc}_G$</td>
<td>3</td>
<td>1</td>
<td>3</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

For instance $\text{ch}^{-1} \text{cyc}_H$ has value $\frac{1}{4} 2z_{(4)} = 2$ on 4-cycles. Observe that $\text{ch}^{-1} \text{cyc}_H$ is the permutation character of $\text{Sym}_4$ acting on the cosets of $H$, and similarly for $G$.

More generally we have the following lemma.
Lemma 5.12. Let $G \leq \text{Sym}_n$ be a permutation group. Then $\text{ch} \, \text{cyc}_G$ is the permutation character of $\text{Sym}_n$ acting on the cosets of $G$.

Proof. Suppose that $G$ has $m_\lambda$ elements of cycle type $\lambda$. By (5.6),

$$\text{ch}^{-1} \text{cyc}_G = \phi$$

where $\phi \in \text{Cl}(\text{Sym}_n)$ is the class function defined by

$$\phi(\sigma) = \frac{z_{\text{cyc type}(g)}}{|G|} m_{\text{cyc type}(\sigma)}.$$ 

Let $\pi$ be the permutation character of $S_n$ acting on the cosets of $G$. Thus $\pi(\sigma)$ is the number of cosets $G\tau$ such that $G\tau\sigma = G\tau$. Equivalently, $\tau\sigma\tau^{-1} \in G$. Therefore

$$\pi(\sigma\lambda) = \frac{1}{|G|} \left| \{ \tau \in \text{Sym}_n : \tau\sigma\lambda\tau^{-1} \in G \} \right| = \frac{z_\lambda}{|G|} m_\lambda.$$ 

where the second inequality uses that $z_\lambda$ is the size of the centralizer of a permutation of cycle type $\lambda$. Comparing (5.7) and (5.8) we get the required conclusion. □

5.7. Pólya’s Cycle Index Theorem. Pólya’s Theorem concerns the action of $\text{Sym}_n$ on the set $W_n$ of words of length $n$ with entries from $\mathbb{N}$. Given $w \in W_n$ let $\text{cont}(w)$ be the composition $\alpha$ of $n$ such that $\alpha_i$ is the number of entries of $w$ equal to $i$. As seen in , the symmetric group $\text{Sym}_n$ acts on the set of such words by place permutation: $(w\sigma)_i = w_{i\sigma^{-1}}$. Given a permutation subgroup $G \leq \text{Sym}_n$ let $W_n/G$ denote the set of orbits of $G$ on $W_n$. We write $\text{cont}([w])$ for the common content of words in the orbit of $w$. Observe that if $\alpha$ is a composition rearranging to the partition $\lambda$ then the number of orbits with content $\alpha$ and $\lambda$ agree. We may therefore enumerate all the orbits by the symmetric function

$$\text{enum}_G = \sum_{\lambda} c_\lambda \text{mon}_\lambda$$

where the sum is over all partitions of $n$ and $c_\lambda$ is the number of orbits of content $\lambda$.

Example 5.13. Let $H = \langle (1,2,3,4) \rangle \leq \text{Sym}_4$. Then $W_4/H$ is the set of 4-bead necklaces, where two necklaces are identified if they are equal up to a rotation. There are two necklaces with content $(2,2)$, namely 1122 and 1212, and six necklaces with content $(1,1,1,1)$, namely 1234, 1243, 1324, 1342, 1423, 1432. Note that, by Example 5.11(3), these are the coefficients of $\text{mon}_{(2,2)}$ and $\text{mon}_{(1,1,1,1)}$ in $\text{cyc}_H$. We leave it as an exercise to check the other coefficients, and the corresponding result for $W_4/G$, thought of as the set of 4-bead necklaces up to both rotation and reflection.

Pólya’s Theorem says this holds in general.
Theorem 5.14. Let $G \leq \text{Sym}_n$ be a permutation group and let $\lambda$ be a partition of $n$. The coefficient of $\text{mon}_\lambda$ in $\text{cyc}_G$ is the number of orbits of $G$ on $W_n$ with content $\lambda$.

Proof. Let $m_{\lambda}$ be the number of orbits of $G$ on $W_n$ with content $\lambda$. The subset $W_{\lambda}$ of $W_n$ of words with content $\lambda$ is, as a $\text{Sym}_n$-set, equivalent to the coset space $\text{Sym}_\lambda \setminus \text{Sym}_n$, where $\text{Sym}_\lambda$ is the Young subgroup for $\lambda$ seen in §5.1. Therefore $m_{\lambda}$ is the number of double cosets $\text{Sym}_\lambda \sigma G$ for $\sigma \in \text{Sym}_n$. Now

$$[\text{mon}_\lambda] \text{cyc}_G = \langle h_{\lambda}, \text{cyc}_G \rangle$$

$$= \langle \pi^\lambda, 1^\text{Sym}_n \rangle_{\Lambda_n}$$

$$= \langle 1^\text{Sym}_\lambda, 1^\text{Sym}_n \rangle_{\text{Sym}_n}$$

$$= \langle 1^\text{Sym}_\lambda \downarrow_{G}, 1_G \rangle_G$$

$$= m_{\lambda}$$

where the equalities hold by the duality between the monomial and complete symmetric functions in Theorem 5.2, Theorem 5.8, the interpretation of $\pi^\lambda$ as a permutation character, Frobenius reciprocity and finally Mackey’s Theorem (or the well known connection between permutation characters and orbit counting). □

See Exercise 32 below for the connection between Pólya’s Theorem and the more basic orbit counting method using the result commonly known as Burnside’s Lemma.

6. PROBLEMS

Hints, references or solutions for these problems are given in the final section.

(Lecture 1) Gale–Ryser Theorem and dominance order

1. Let $\lambda$ be a partition.

(a) Show that there is a unique 0-1 matrix with row sums $\lambda$ and column sums $\lambda'$. [Hint: for existence, use the Young diagram of $\lambda$.]

(b) Suppose that $\mu \triangleleft \lambda'$. By the Gale–Ryser Theorem (the direction not proved in Lecture 1), there is a 0-1 matrix with row sums $\lambda$ and column sums $\mu$. Assuming this, prove that there are at least two such matrices.

2. (a) Let $\lambda$ and $\nu$ be partitions of $n$. Show that $\lambda$ and $\nu$ are neighbours in the dominance order (i.e. $\lambda \triangleright \nu$ and if $\lambda \trianglerighteq \mu \trianglerighteq \nu$ then either $\lambda = \mu$ or $\mu = \nu$) if and only if $[\nu]$ can be obtained from $[\lambda]$ by
moving a single box of $[\lambda]$ down to the first available position below it.

For example, $\lambda = (4, 4, 3, 1)$ and $\nu = (4, 3, 3, 2)$ are neighbours in the dominance order, obtained by moving the box $(2, 4) \in [\lambda]$ to the first available position $(4, 2) \in [\nu]$. If instead $(2, 4)$ is moved to $(5, 1)$ we get a neighbour of $\nu$, but not of $\lambda$:

(b) Let $\alpha$ and $\beta$ be partitions of $n$. Show that $\alpha \succeq \beta$ if and only if $\alpha' \subseteq \beta'$. (In particular, this implies that the condition $\lambda' \succeq \mu$ in the Gale–Ryser theorem is symmetric with respect to $\lambda$ and $\mu$.)

(Lectures 2 and 3) Newton’s Identities

3. Newton’s Identity $\sum_{k=0}^{n} (-1)^k h_{n-k} e_k = 0$ was proved using the generating functions $H(t) = \sum_{n=0}^{\infty} h_n t^n = \prod_{i=1}^{\infty} (1 - x_i t)^{-1}$ and $E(t) = \sum_{n=0}^{\infty} (-1)^n e_n t^n = \prod_{i=1}^{\infty} (1 - x_i t) = H(t)^{-1}$.

This exercise gives some related identities involving the power sum symmetric functions $p_k = \text{mon}_{(k)} = x_1^k + x_2^k + \cdots$ that have similar short proofs using generating functions.

(a) Let $Q(t) = \sum_{k=1}^{\infty} p_k t^k / k$. Show that $Q(t) = - \sum_{i=1}^{\infty} \log(1 - x_i t)$.

(b) From (a), or directly, prove that $\sum_{k=1}^{\infty} p_k t^k = \sum_{i=1}^{\infty} x_i t / (1 - x_i t)$.

(c) Prove that $t H'(t) = t Q'(t) H(t)$.

(d) Deduce that $n h_n = \sum_{k=1}^{n} p_k h_{n-k}$.

(e) Prove an identity analogous to (d) for $n e_n$.

(f) Prove that $p_n = \sum_{k=0}^{n-1} (-1)^k (n-k) h_{n-k} e_k$.

(g) For $\mu \vdash n$ define $p_\mu = p_{\mu_1} \cdots p_{\mu_l(\mu)}$. Show that $\{ p_\mu : \mu \vdash n \}$ is a basis for $\Lambda_n$.

(h) Show that $\exp Q(t) = H(t)$.

(Lecture 2) Complete homogeneous symmetric functions and another version of the complete/elementary duality.

4. Give a combinatorial interpretation to the coefficients $M_{\lambda \mu}$ expressing the complete homogeneous symmetric functions in the monomial basis,

$$ h_\mu = \sum_{\lambda} M_{\lambda \mu} \text{mon}_\lambda $$
analogous to Lemma 1.3. In particular show that the matrix $M$ is symmetric.

5. Let $\mu$ be a partition of $n$. Define a change of basis matrix $R$ by

$$h_\mu = \sum_\lambda R_{\lambda\mu} e_\lambda.$$ 

(a) Show that $R_{\mu\mu} = (-1)^{n-\ell(\mu)}$.

(b) Show that if $R_{\lambda\mu} \neq 0$ then $\mu \succeq \lambda$.

(c) Show that $R_{(1^n)\mu} = 1$ for all $\mu \vdash n$. [Hint: consider the coefficient of $x_1^n$ in $h_\mu$.]

(d) Show that $R_{(2,1^{n-2})\mu} = -n + \ell(\mu)$.

(e) Show that $R$ is self-inverse, or equivalently, $e_\mu = \sum_\lambda R_{\lambda\mu} h_\lambda$. [Hint: use the $\omega$ involution in Question 10.]

(Lecture 2) MacMahon’s Master Theorem

6. Let $a$, $b$, $c \in \mathbb{N}_0$. Use MacMahon’s Master Theorem to prove the following generalization of Dixon’s Identity

$$\sum_k (-1)^k \binom{a + b}{a + k} \binom{b + c}{b + k} \binom{c + a}{c + k} = \frac{(a + b + c)!}{a!b!c!}.$$ 

7. Given a composition $\alpha$ of $n$ let $v(\alpha) = (1, \ldots, 1, \ldots, n, \ldots, n)$ where the number $j$ appears exactly $\alpha_j$ times. Let $d_\alpha$ be the number of sequences $(u_1, \ldots, u_n)$ such that $\{u_1, \ldots, u_n\} = \{1, \ldots, n\}$ and $u_i \neq v(\alpha)_i$ for any $i$.

(a) Show that $d_{(1^n)}$ is the number of permutations of $\{1, \ldots, n\}$ with no fixed points. (Such permutations are called derangements.)

(b) Let $e_n$ be the number of derangements of $\{1, \ldots, n\}$ with sign $+1$ and let $o_n$ be the number of derangements of $\{1, \ldots, n\}$ with sign $-1$. By evaluating the determinant of the matrix

$$
\begin{pmatrix}
0 & 1 & \cdots & 1 \\
1 & 0 & \cdots & 1 \\
\vdots & \vdots & \ddots & \vdots \\
1 & 1 & \cdots & 0
\end{pmatrix}
$$

in two different ways, show that $o_n - e_n = (-1)^n(n - 1)$. [For an alternative proof see Question 9(b).]

Now suppose that $\ell(\alpha) = m$. Work with symmetric functions in $m$ variables $x_1, \ldots, x_m$. 

(c) Show that \( d_\alpha = [x^\alpha] (p_1(x) - x_1)^{a_1} \cdots (p_1(x) - x_m)^{a_m} \) where
\[
p_1(x) = p_1(x_1, \ldots, x_m) = x_1 + \cdots + x_m.
\]

(d) Deduce from MacMahon's Master Theorem that
\[
d_\alpha = [x^\alpha] \det \left( \begin{array}{cccc} 1 & -x_1 & \cdots & -x_1 \\ -x_2 & 1 & \cdots & -x_2 \\ \vdots & \vdots & \ddots & \vdots \\ -x_m & -x_m & \cdots & 1 \end{array} \right)^{-1}.
\]

(e) Using (b) and (d) deduce that
\[
d_\alpha = [x^\alpha] \frac{1}{1 - e_2(x) - 2e_3(x) - \cdots - (m-1)e_m(x)}.
\]

(f) Show that
\[
(1 - e_2(x) - 2e_3(x) - \cdots)(1 + d(1)e_1 + d(12)e_2 + d(13)e_3 + \cdots) = 1 + f
\]
where every monomial summand in \( f \) is divisible by some \( x_i^2 \).
Hence show that
\[
d_{(1^n)} = \binom{n}{2} d_{(1^{n-2})} + 2 \binom{n}{3} d_{(1^{n-3})} + \cdots + (n-1) \binom{n}{n} d_{(1^{n-1})}
\]
for every \( n \in \mathbb{N} \).

(g) Prove more generally that if \( \ell \in \mathbb{N} \) and \( n \geq \ell \) then
\[
d_{(1^n)} = \frac{n!}{\ell!} d_{(1^\ell)} + (-1)^{\ell+1} \sum_{m=\ell+1}^{n} \binom{m-1}{\ell} \binom{n}{m} d_{(1^{n-m})}.
\]

[This question is based on §71 of MacMahon, *Combinatory Analysis Vol. I*. According to MacMahon, the identity in (f) was not known before the Master Theorem. It has a short proof using generating functions, which is the only way I know to prove (g); this identity is maybe not so easy to discover without the Master Theorem.]

(Lecture 3) Power sum symmetric functions and cycle indices.

8. Recall that if \( \lambda \) is a partition of \( r \) with exactly \( a_i \) parts of size \( i \), for each \( i \in \{1, \ldots, r\} \), then
\[
z_\lambda = 1^{a_1} 2^{a_2} \cdots r^{a_r} a_1! a_2! \cdots a_r!.
\]

(a) Prove that \( z_\lambda \) is the size of the centralizer in Sym_n of an element of cycle-type \( \lambda \). (Or, more combinatorially, you might prefer to prove that \( n!/z_\lambda \) is the size of the conjugacy class, and deduce the result for centralizers.)

(b) Prove that \( \sum_{\lambda \vdash r} \frac{p_\lambda}{z_\lambda} = h_r \).
(c) What is the analogous identity for elementary symmetric functions?

9. (a) Consider the specialization \( p_k \mapsto (-1)^{k-1} \) for \( k \in \mathbb{N} \). Let \( \lambda \) be a partition of \( n \). Show that \( p_\lambda \mapsto \text{sgn} \sigma_\lambda \) where \( \sigma_\lambda \) is a permutation of cycle-type \( \lambda \).

(b) Let \( o_n \) be the number of derangements in \( \text{Sym}_n \) that are odd permutations, and let \( e_n \) be the number of derangements in \( \text{Sym}_n \) that are even permutations. By specializing the Cycle Index Formula, prove that \( o_n - e_n = (-1)^n(n-1) \) for all \( n \in \mathbb{N}_0 \).

(c) [American Mathematical Monthly Problem 11668] Let \( O_n \) be the number of derangements of \( \{1, 2, \ldots, n\} \) with an odd number of cycles in their disjoint cycle decomposition, and let \( E_n \) be the number of derangements of \( \{1, 2, \ldots, n\} \) with an even number of cycles in their disjoint cycle decomposition. Prove that \( O_n - E_n = n - 1 \) for all \( n \in \mathbb{N}_0 \).

10. Let \( \omega : \Lambda \rightarrow \Lambda \) be the ring homomorphism defined by \( \omega(h_n) = e_n \). Use Newton’s Identity to show that \( \omega(e_n) = h_n \). Show also that \( \{p_\lambda : \lambda \vdash n\} \) is a basis of \( \Lambda_n \) consisting of eigenvectors for \( \omega \) and determine the eigenvalues.

(Lecture 4) Schur functions

11. Let \( \lambda \) and \( \mu \) be partitions of \( n \).
   (a) Show that if \( \text{SSYT}(\lambda, \mu) \neq \emptyset \) then \( \lambda \succeq \mu \).
   (b) Show, conversely, that if \( \lambda \succeq \mu \) then \( |\text{SSYT}(\lambda, \mu)| \geq 1 \).
   (c) It follows from (a) that
   \[
   s_\lambda = \sum_{\mu \subseteq \lambda} K_{\lambda \mu} \text{mon}_\mu
   \]
   where \( K_{\lambda \mu} = |\text{SSYT}(\lambda, \mu)| \). (These are the Kostka numbers.) Show that \( K_{\lambda \lambda} = 1 \) and deduce that \( \{s_\lambda : \lambda \vdash n\} \) is a basis for \( \Lambda_n \).
   (d) Show that \( s_{(n-a,a)}(x_1, x_2) = \sum_{a \leq b \leq n/2} \text{mon}_{(n-b,b)}(x_1, x_2) \).

(Lecture 4) Jacobi–Trudi Identity

12. Give a proof of the general Jacobi–Trudi Identity by generalizing Example 2.2. In particular, show that the symmetric function obtained by expanding the determinant by choosing \( h_{\lambda \mu - \nu - j} \) from
column \( j \) for each \( j \in \{1, \ldots, M\} \) is the signed weight of the path tuples \((P_1, \ldots, P_M)\) such that \( P_j \), the path starting at \((M - j, 1)\), finishes at \((M - j\sigma + \lambda_{j\sigma}, N)\) for each \( j \).

13. Another version of the ‘proof-by-example’ of Theorem 2.1 had an error, pointed out to me by Darij Grinberg. Suppose, in the setting of Example 2.2, we define a map \( K : A\backslash S \to A\backslash S \) on path triples \((P_1, P_2, P_3)\) with at least one intersection as follows:

(a) choose \( i \) minimal such that \( P_i \) meets another path;
(b) choose \( j \) minimal such that \( P_i \) meets \( P_j \);

then (as before) swap \( P_i \) and \( P_j \) after their first intersection. Show that \( K \) is not an involution.

14. Let \( \lambda \) be a partition with \( M \geq \ell(\lambda) \). Applying the \( \omega \) involution to the Jacobi–Trudi Identity gives

\[
{s_{\lambda'}} = \det \begin{pmatrix}
  e_{\lambda_1} & e_{\lambda_1+1} & \cdots & e_{\lambda_1+(M-1)} \\
  e_{\lambda_2-1} & e_{\lambda_2} & \cdots & e_{\lambda_2+(M-2)} \\
  \vdots & \vdots & \ddots & \vdots \\
  e_{\lambda_M-(M-1)} & e_{\lambda_M-(M-2)} & \cdots & e_{\lambda_M}
\end{pmatrix}
\]

Give an involutive proof of this identity.

\textit{A polarization identity: see MathOverflow 61884}

15. (a) Let \( N, n \in \mathbb{N} \). Let

\[
P(x_1, \ldots, x_N) = \sum_{I \subseteq \{1, \ldots, N\}} (-1)^{n-|I|} \left( \sum_{i \in I} x_i \right)^n.
\]

Show that

\[
P(x_1, \ldots, x_N) = \begin{cases} 0 & \text{if } n < N \\ N!x_1 \ldots x_N & \text{if } n = N. \end{cases}
\]

(b) Hence show that if \( V \) is a \( \mathbb{C} \)-vector space and \( f : V \times \cdots \times V \to \mathbb{C} \) is an \( n \)-multilinear form symmetric in its variables then

\[
f(v_1, \ldots, v_n) = \frac{1}{n!} \sum_{I \subseteq \{1, \ldots, n\}} (-1)^{n-|I|} g(\sum_{i \in I} v_i)
\]

where \( g(u) = f(u, \ldots, u) \) for \( u \in V \). (A special case is the well known polarization identity \( 2f(v, v') = f(v + v', v + v') - f(v, v) - f(v', v') \).)

(c) Express \( P \) in the monomial basis of symmetric polynomials in \( N \) variables when \( n > N \).

\textit{(Lecture 6) Young’s Rule}
16. Let $\lambda$ be a partition of $n$ and let $r \in \mathbb{N}_0$. Let $Y_r(\lambda)$ be the set of partitions $\mu$ such that $[\mu]$ is obtained from $[\lambda]$ by adding $r$ boxes, no two in the same column. Prove Young’s Rule that

$$a_{\lambda+\delta}h_r(x_1, \ldots, x_N) = \sum_{\mu \in Y_r(\lambda), \ell(\mu) \leq N} a_{\mu+\delta}$$

using a sign-reversing involution on the set

$$\mathcal{P} = \{(A, S) : A \in \mathrm{Abc}(\lambda), S \text{ a multiset of } \{1, \ldots, N\}, |S| = r\}.$$ 

17. Let $\ell \in \mathbb{N}$ and let $\lambda$ be a partition of $n \in \mathbb{N}_0$ with $\ell$-core $\gamma$. Let $(\lambda(0), \ldots, \lambda(\ell-1))$ be the $\ell$-quotient of $\lambda$. Let $n = |\gamma| + w\ell$ and let $\alpha = (1^{\ell-1}, \ell^{\ell}).$ Show that

$$\chi(\lambda)(\alpha) = \pm f_{\lambda(0)} f_{\lambda(1)} \ldots f_{\lambda(\ell-1)}.$$

18. Use 2-quotients of partitions to prove the following identity of Gauss:

$$\sum_{n=0}^{\infty} x^{n(n+1)} = \frac{(1-x^2)(1-x^4)(1-x^6)\ldots}{(1-x)(1-x^3)(1-x^5)\ldots}.$$

19. Let $\ell, m \in \mathbb{N}$ be coprime.

(a) Show that $\ell m - \ell - m$ is the largest number that cannot be expressed in the form $a\ell + bm$ where $a, b \in \mathbb{N}_0$. [Hint: show that if $N$ is the largest such number then $N \leq \ell m$, $N + \ell$ is a multiple of $m$ and $N + m$ is a multiple of $\ell$.]

(b) Using (a) and the abacus, show that there are only finitely many partitions that are simultaneous $\ell$-cores and $m$-cores.

(c) Prove that the number of simultaneous $\ell$-core and $m$-core partitions is

$$\frac{1}{\ell + m} \binom{\ell + m}{\ell}.$$ 

An alternative proof of the Murnaghan–Nakayama rule

20. Observe that $p_2 = 2h_2 - h_1^2$. Using Young’s rule, show that if $\lambda$ is any partition then

$$s_{\lambda}(2h_2 - h_1^2) = \sum_{\mu = \lambda + \Box} s_{\mu} - \sum_{\nu = \lambda + \Box} s_{\nu},$$

where the notation indicates that $\mu$ is obtained from $\lambda$ by adding a 2-hook consisting of two boxes in the same row, and $\nu$ is obtained from
\( \lambda \) by adding a 2-hook consisting of two boxes in the same column. Deduce the Murnaghan–Nakayama rule for the product \( s_\lambda p_2 \).

21. Generalizing the previous question, use Question 3(f) and the Young and Pieri rules to prove the Murnaghan–Nakayama rule by a cancelling involution.

**Lecture 8** Lascoux–Schützenberger involution

22. Let \( \lambda \) be a partition such that \( \ell(\lambda) \leq N \).
   
   (a) Let \( \sigma \in \text{Sym}_N \) and suppose that \( j\sigma > (j+1)\sigma \). Show that if \( \beta = \lambda \cdot \sigma \) then \( \beta_j > \beta_{j+1}\sigma \).
   
   (b) Deduce that if \( \tau \in \text{Sym}_N \) and \( \lambda \cdot \tau \) is a partition then \( \tau = \text{id}_{\text{Sym}_N} \).
   
   (c) Hence show that the orbit \( \{ \lambda \cdot \sigma : \sigma \in \text{Sym}_N \} \) has size \( N! \). (Of course, as seen in Example 4.8, some elements in the orbit may have negative coefficients.)

23. Fix \( \ell \in \mathbb{N}_0 \). Let \( S \) be the set of words of length \( \ell \) with entries + and –. Read from left to right, say that a – in \( w \) is bad if it sets a new record for the excess of – over +. A – is good if it is not bad. For example, in \(+ – + + + – – – \) the – in position 3 and the – in position 8 are bad and the others are good.

For \( m, n \in \mathbb{N}_0 \), let \( S(m, n) \) be the set of words in \( S \) having – entries in exactly \( n \) positions, such that at least \( m \) of these entries are good.

(Not that all words have length \( \ell \).)

(a) Let \( m \in \mathbb{N}_0 \) and let \( n \in \mathbb{N} \). By adapting the coplactic maps define a bijection

\[
S(m, n) \setminus S(m + 1, n) \to S(m, n - 1) \setminus S(m + 1, n - 1).
\]

(b) Hence define a bijection \( S(m, n) \setminus S(m + 1, n) \to S(m, m) \).

(c) Hence prove Theorem 15.14 in [6].

24. Recall that \( \delta = (N-1, N-2, \ldots, 2, 1) \). Let \( \lambda \) be a partition with \( \ell(\lambda) \leq N \). and let \( \text{SSYT}_{\leq N}(\lambda) \) denote the set of semistandard \( \lambda \)-tableaux with entries from \( \{1, \ldots, N\} \). Use a sign-reversing involution and the coplactic maps to prove that

\[
\sum_{A \in \text{Abc}(\emptyset)} \sum_{t \in \text{SSYT}_{\leq N}(\lambda)} x^A x^T \text{sgn}(A) = \sum_{A' \in \text{Abc}(\lambda)} x^{A'} \text{sgn}(A')
\]

and deduce that \( s_\lambda(x_1, \ldots, x_N) = a_{\delta+\lambda}/a_{\delta} \).

**Lecture 9** Corollaries of \( a_{\lambda+\delta}/a_{\delta} = s_\lambda(x_1, \ldots, x_N) \)
25. (a) Deduce the equivalent forms of Pieri’s Rule and Young’s Rule from Theorems 3.7 and 3.8, respectively:

\[ h_\mu = \sum_{\lambda \vdash n} |\text{SSYT}(\lambda, \mu)| s_\lambda \]

\[ e_\mu = \sum_{\lambda \vdash n} |\text{SSYT}(\lambda, \mu)| s_\lambda. \]

(b) The \( \omega \)-involution was defined by \( \omega(h_n) = e_n \) for \( n \in \mathbb{N}_0 \). Show that \( \omega(s_\lambda) = s_{\lambda'} \) for all partitions \( \lambda \).

(Lecture 10) Dual bases

26. Prove Claim 4 in the proof of Theorem 5.3, that

\[ h_\mu = \sum_{\alpha \vdash n} \frac{p_\alpha}{z_\alpha} \pi^\mu(\alpha). \]

(Lecture 10) Skew-Schur functions. A skew-tableau is semistandard if its rows are weakly increasing from left to right and the columns are strictly increasing from top to bottom. For example, the skew-tableau shown below is semistandard.

```
1 1
1 2
1 3
4
```

27. Let \( \lambda/\nu \) be a skew-partition of \( n \). Generalizing the combinatorial definition of Schur functions, define

\[ s_{\lambda/\nu} = \sum_{T \in \text{SSYT}(\lambda/\nu)} x^T. \]

For \( \alpha \) a composition of \( n \), let \( K_{\lambda/\nu, \alpha} = |\text{SSYT}(\lambda/\nu, \alpha)| \) be the number of semistandard Young tableaux of shape \( \lambda/\nu \) and content \( \alpha \).

(a) Generalize the Bender–Knuth involution to show that \( s_{\lambda/\nu} \) is a symmetric function.

(b) Use Young’s Rule to show that \( \langle s_\lambda, s_\nu h_\alpha \rangle = K_{\lambda/\nu, \alpha} \).

(c) Use the orthogonality of the complete symmetric and monomial symmetric functions to show that \( \langle s_{\lambda/\nu}, h_\alpha \rangle = K_{\lambda/\nu, \alpha} \).

(d) Hence show that \( \langle s_\lambda, s_\nu f \rangle = \langle s_{\lambda/\nu}, f \rangle \) for any \( f \in \Lambda \).

Murnaghan–Nakayama Rule for skew-Schur functions

28. Generalize the definition of border-strip tableaux to tableaux of skew shape and prove a version of the Murnaghan–Nakayama rule for skew-Schur functions.
Jacobi–Trudi Rule for skew-partitions

29. Let $\lambda/\nu$ be a skew-partition. Let $M \geq \ell(\lambda)$. Prove that

$$s_{\lambda/\nu} = \det \begin{pmatrix} h_{\lambda_1-v_1} & h_{\lambda_2-v_1+1} & \cdots & h_{\lambda_1-v_M+(M-1)} \\ h_{\lambda_2-v_1-1} & h_{\lambda_2-v_2} & \cdots & h_{\lambda_2-v_M+(M-2)} \\ \vdots & \vdots & \ddots & \vdots \\ h_{\lambda_M-v_1-(M-1)} & h_{\lambda_M-v_2-(M-2)} & \cdots & h_{\lambda_M-v_M} \end{pmatrix}$$

Deduce that

$$s_{\lambda/\nu} = \sum_{\sigma \in \text{Sym}_M} h_{\lambda,\sigma-v} \text{sgn}(\sigma).$$

Lascoux–Schützenberger involution for skew-tableaux

30. Extend the word map $w$, the coplactic maps and the Lascoux–Schützenberger involution to skew-tableaux of a fixed shape and prove a generalization of Lemma 4.7.

Littlewood–Richardson Rule

31. Let $\lambda/\nu$ be a skew-partition of $n$ and let $\mu$ be a partition of $m$ with $\ell(\mu) \leq N$. Let $c^\lambda_{\mu\nu}$ be the number of semistandard $\lambda/\nu$ skew-tableaux $t$ of content $\nu$ such that $w(t)$ is latticed. The Littlewood–Richardson Rule states that

$$\langle s_\mu s_\nu, s_\lambda \rangle = c^\lambda_{\mu\nu}.$$

Prove the Littlewood–Richardson Rule using this outline.

(a) Show, using Question 26(d), that the Littlewood–Richardson rule is equivalent to $s_{\lambda/\nu} = \sum_\mu c^\lambda_{\mu\nu} s_\mu$.

(b) Using Theorem 2.1, show that

$$\langle s_{\lambda/\nu}, s_\mu \rangle = \sum_{\sigma \in \text{Sym}_N} \langle s_{\lambda/\nu}, h_{\mu,\sigma} \text{sgn}(\sigma) \rangle.$$ 

(c) Deduce from Question 27 that

$$\langle s_{\lambda/\nu}, s_\mu \rangle = \sum_{\sigma \in \text{Sym}_N} |\text{SSYT}(\lambda/\nu, \mu \cdot \sigma)| \text{sgn}(\sigma).$$

(d) Using Question 30, show that the right-hand side above is $c^\lambda_{\mu\nu}$.

Pólya’s Cycle Index Theorem

32. (a) Let $G \leq \text{Sym}_n$ be a permutation group and consider the orbits of $G$ on words in $W_n$ with entries from $\{1, \ldots, c\}$. Deduce from Pólya’s Theorem that the number of such orbits is

$$\frac{1}{|G|} \sum_{g \in G} c^{\ell(\text{cycle}(g))}.$$
Remark: this result can also be proved using that the number of orbits of a group $G$ on a set $\Omega$ is $\frac{1}{|G|}\sum_{g \in G} |\text{Fix}_\Omega(g)|$, i.e. the result commonly known as Burnside’s Lemma.

(b) Deduce from (a) and Examples 5.11 and 5.13 that the number of 4 bead necklaces using beads of $c$ colours is $\frac{1}{4}(c^4 + c^2 + 2c)$ up to rotation, and $\frac{1}{8}(c^4 + 2c^3 + 3c^2 + c)$ up to both rotation and reflection.

7. Hints, References or Solutions for Problems

1. For (a), observe that the $\ell(\lambda) \times \ell(\lambda')$-matrix $A$ with $A_{ij} = 1$ if $(i, j) \in [\lambda]$ and $A_{ij} = 0$ otherwise has row sums $\lambda$ and column sums $\lambda'$. For (b), let $A$ be a 0-1 matrix with row sums $\lambda$ and column sums $\mu$. The positions $(i, j)$ with $A_{ij} \neq 1$ do not form a partition diagram (since then we are in the case of (a), with $\mu = \lambda'$). Therefore there exists $(i, j)$ with $A_{ij} = 0$ and either $A_{(i+1)j} = 1$ or $A_{i(j+1)} = 1$. In the former case, since the row sums of $A$ are non-increasing, there exists $j'$ with $A_{ij'} = 1$ and $A_{(i+1)j'} = 0$. Define $A'$ by swapping 0s and 1s in the positions $(i, j), (i+1, j), (i, j'), (i+1, j')$ as indicated below:

$$
\begin{array}{cccc}
0 & \ldots & 1 & 1 \\
1 & \ldots & 0 & 0 \\
\end{array}
\rightarrow
\begin{array}{cccc}
0 & \ldots & 0 & 1 \\
1 & \ldots & 1 & 0 \\
\end{array}
$$

Then $A'$ has the same row and column sums as $A$. The latter case is similar.

2. For (a), see [5, Theorem 1.4.10]. By (a), $a \triangleright \triangleright \beta$ if and only if $[\beta]$ can be obtained from $[\alpha]$ by repeatedly moving boxes from higher rows to lower rows, so if and only if $[\beta']$ can be obtained from $[\alpha']$ by repeatedly moving boxes from lower rows to higher rows. Hence $a \triangleright \triangleright \beta$ if and only if $\beta' \triangleright \triangleright \alpha'$.

3. We have

$$Q(t) = \sum_{k=1}^{\infty} p_k \frac{t^k}{k} = \sum_{k=1}^{\infty} \sum_{l=1}^{\infty} x_l^k \frac{t^k}{k} = \sum_{i=1}^{\infty} -\log(1 - x_i t).$$

Differentiating with respect to $t$ we get

$$Q'(t) = \sum_{k=1}^{\infty} p_k t^k = \sum_{i=1}^{\infty} \frac{x_i}{1 - x_i t}.$$ 

On the other hand, differentiating $H(t) = \prod_{i=1}^{\infty} 1/(1 - x_i t)$ using the product rule gives

$$H'(t) = \sum_{i=1}^{\infty} \frac{x_i}{1 - x_i t} H(t)$$

(7.1)
so we have $H'(t) = H(t)Q'(t)$. Multiply through by $t$ to get $tH'(t) = H(t)(tQ'(t))$; now take coefficients of $t^n$ to get $nh_n = \sum_{k=1}^n h_{n-k}p_k$. This proves (a), (b), (c), (d).

For (e), argue in a similar way using $E(t) = \prod_{i=1}^\infty (1-x_it)$; (f) then follows from the identity

$$tH'(t)E(-t) = \sum_{i=1}^\infty \frac{x_it}{1-x_it} = tQ(t).$$

The standard argument, used for example in Proposition 1.5, now shows that $\{p_\lambda : \lambda \vdash n\}$ is a basis for $\Lambda_n$, as stated in (g). See (1.5) for (h).

**Remark.** See Claim 4 in the proof of Theorem 5.3 for a combinatorial interpretation of the coefficients in the transition matrix expressing each $h_{\mu}$ as a linear combination of $p_\lambda$. As observed in Remark (2) in §1.9, these coefficients are rational but not necessarily integral.

4. $M_{\lambda\mu}$ is the number of $\ell(\lambda) \times \ell(\mu)$-matrices with row sums $\lambda$, column sums $\mu$ and entries in $\mathbb{N}$. This can be proved in the same way as Lemma 1.2; use the $j$th column of such a matrix $Z$ to record the monomial chosen from the $j$th bracket in

$$h_\mu = \prod_{j=1}^{\ell(\mu)} h_{\mu_j} = \prod_{j=1}^{\ell(\mu)} (x_1^{\mu_j} + \cdots + x_1^{\mu_j-1} x_2 + \cdots + \cdots)$$

in a sequence of choices whose product is the monomial $x^\lambda$.

5. By Newton’s Identity (1.2), we have

$$h_k = (-1)^{k-1}e_k + (-1)^{k-2}e_{k-1}h_1 + \cdots + (-1)^{k-j-1}e_{k-j}h_j + \cdots + h_{k-1}e_1$$

for each $k \in \mathbb{N}_0$. It follows inductively that if $\mu \vdash n$ then

$$h_\mu = (-1)^{n-\ell(\mu)}e_\mu + f$$

where $f$ is an integral linear combination of elementary symmetric functions labelled by partitions $\lambda$ such that $\mu \triangleright \lambda$. This proves (a) and (b).

Let $\mu \vdash n$. Since $[x_1^n]h_\mu = 1$ whereas $[x_1^n]e_\mu = 0$ unless $\mu = (1^n)$, we have $R_{\mu(1^n)} = 1$ for any $\mu$. Similarly $[x_1^{n-1}x_2]h_\mu = \ell(\mu)$, since we must choose a unique $h_{\mu_j}$ in the product $h_\mu = h_{\mu_1} \cdots h_{\mu_{\ell(\mu)}}$ from which to take $x_1^{\mu_j-1}x_2$, whereas

$$[x_1^{n-1}x_2]e_\mu = \begin{cases} n & \text{if } \mu = (1^n) \\ 1 & \text{if } \mu = (2,1^{n-2}) \\ 0 & \text{otherwise.} \end{cases}$$

Since $h_\mu = \cdots + R_{(2,1^{n-2})\mu}e_{(2,1^{n-2})} + e_{(1^n)}$, it follows that $\ell(\mu) = R_{(2,1^{n-2})\mu} + n$, hence $R_{(2,1^{n-2})\mu} = -n + \ell(\mu)$. This proves (c) and (d).
Finally (e) follows immediately from the $\omega$ involution, which swaps $e_\mu$ and $h_\mu$ for each $\mu$. (Is there a combinatorial interpretation of this symmetry?)

**Remark.** Computer algebra can be useful for exploring the transition matrices between the different bases of $\Lambda$. In Magma [2], the matrix $R$ above is the transpose of HomogeneousToElementaryMatrix(n). In SAGE [15] one can create $\Lambda$ by

$$\text{Sym = SymmetricFunctions(QQ)};$$

then Sym.inject_shorthands() sets up conversions between the different bases. For example $h(e^{[3]})$ evaluates to $h[1,1,1]-2*h[2,1]+h[3]$, giving the coefficients in the first column of $R$ when $n = 3$.

6. See [4].

7. For (a) to (f), see MacMahon’s book, cited in the question. For (g), which generalizes (f), recall that the exponential generating function for the derangement numbers $d_{(1^n)}$ is $\exp(-t)/(1 - t)$. Therefore

$$\frac{1}{n!} \sum_m \binom{m-1}{\ell} \binom{n}{m} d_{(1^{n-m})}$$

is the coefficient of $t^n$ in

$$\left( \sum_m \binom{m-1}{\ell} \frac{t^m}{m!} \right) \frac{\exp(-t)}{1 - t}.$$

(Note that the sum is now over all $m$, so there is a non-zero contribution when $m = 0$.) By the claim below, this simplifies to

$$\frac{(-1)^\ell}{1 - t} (1 - t + \frac{t^2}{2!} - \cdots + (-1)^\ell \frac{t^\ell}{\ell!}) = A_\ell(t) + (-1)^\ell \frac{d_{(1^n)}}{\ell!} \frac{t^\ell}{1 - t}$$

where $A_\ell(t)$ is a polynomial of degree at most $\ell - 1$. Taking out the contribution from $m = 0$ we get

$$(-1)^\ell \frac{d_{(1^n)}}{n!} + \frac{1}{n!} \sum_{m=\ell+1}^n \binom{m-1}{\ell} \binom{n}{m} d_{(1^{n-m})} = (-1)^\ell \frac{d_{(1^n)}}{\ell!}$$

for all $n \geq \ell$. This rearranges to give the claimed identity.

**Claim.** If $\ell \in \mathbb{N}$ then

$$\sum_m \binom{m-1}{\ell} \frac{t^m}{m!} = (-1)^\ell \exp(t)(1 - t + \frac{t^2}{2!} - \cdots + (-1)^\ell \frac{t^\ell}{\ell!}).$$

**Proof.** Suppose inductively that the left-hand side is $\exp(t)P_\ell(t)$ for some polynomial $P_\ell(t)$. Then for $\ell + 1$ the left-hand side is

$$(t^{-(\ell+1)} \exp(t)P_\ell(t)) \frac{t^{\ell+2}}{\ell+1}.$$
Hence the right-hand side for $\ell + 1$ is $\exp(t)P_{\ell+1}(t)$ where

$$P_{\ell+1}(t) = \frac{(t - \ell - 1)P_{\ell}(t) + tP'_{\ell}(t)}{\ell + 1}.$$  

It is routine to check that the polynomials

$$Q_{\ell}(t) = (-1)^{\ell}(1 - t + \frac{t^2}{2!} - \cdots + (-1)^{\ell}\frac{t^\ell}{\ell!})$$

satisfy this recurrence, hence $P_{\ell}(t) = Q_{\ell}(t)$ for all $\ell \in \mathbb{N}_0$.  

Remark: Darij Grinberg has sent me an easier proof of (g) by induction. He also observed that the result also holds when $\ell = 0$.

8. It is worth noting the group-theoretic refinement of (a): the centralizer of an element of cycle type $\lambda \vdash r$ where $\lambda$ has exactly $a_i$ parts of size $i$ is the wreath product $\prod_i C_i \wr S_{a_i}$, of order $z_{\lambda}$. For (b) use Question 3(h).

The analogous identity for $e_r$, obtained most simply by applying the $\omega$ involution from Question 10, is

$$\sum_{\lambda \vdash r} (-1)^{r-\ell(\lambda)}\frac{p_\lambda}{z_\lambda} = e_r.$$

9. For (b), specialize the version of the Cycle Index Formula in (1.8) by $p_1 \mapsto 0$ and $p_k \mapsto (-1)^{k-1}$. For (c), specialize by $p_1 \mapsto 0$, $p_k \mapsto -1$; this gives

$$\prod_{k=2}^{\infty} \exp(-\frac{1}{k} t^k) = \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{\sigma \in \text{Sym}_n} (-1)^{\text{cyc}(\sigma)}$$

where $\text{cyc}(\sigma) = \text{cyc}_1(\sigma) + \text{cyc}_2(\sigma) + \cdots$ is the number of disjoint cycles in $\sigma$. The left-hand side is $(1 - t) \exp(t)$, so taking coefficients of $t^n$ we get

$$\frac{E_n - O_n}{n!} = \frac{1}{n!} - \frac{1}{(n-1)!} = \frac{1 - n}{n!}$$

hence $O_n - E_n = n - 1$, as claimed.

10. Using Question 33(f), one gets $\omega(p_n) = (-1)^{n-1}p_n$. Therefore $\omega(p_\lambda) = (-1)^{n-\ell(\lambda)}$ if $\lambda \vdash n$. Note that, as seen in 9(a), $(-1)^{n-\ell(\lambda)} = \text{sgn} \sigma_\lambda$, where $\lambda \in \text{Sym}_n$ is a permutation of cycle-type $\lambda$.

11. Part (b) is not nearly as obvious as it might seem: one proof uses the coplactic maps in §4 of the notes. An algebraic proof using the Jacobi–Trudi Identity is given in [5, page 44] and Lemma 5.4 above. For a combinatorial proof of the lemma see Matthew Fayers’ answer to MathOverflow question 226537. A small simplification to this proof is here: wildonblog.wordpress.com/2016/01/05/non-zero-kostka-numbers/.
12. See [13, §4.5], or for the more general version of the Jacobi–Trudi Identity for skew-tableaux, [14, §7.16], where the proof is a short application of a more general involution due to the Lindström and Gessel–Viennot.

13. The problem occurs when we define $P_1$ and $P_3$ by swapping $P_1$ and $P_3$ after their first intersection, and $P_3$ meets $P_2$ after this first intersection, so $P_1$ now meets $P_2 = P_2$. A specific example is shown below.

![Diagram](https://via.placeholder.com/150)

14. Outline. Number the steps of paths from 1. Give a path whose right-steps are step numbers $i_1 < i_2 < \ldots < i_k$ weight $x_{i_1} \ldots x_{i_k}$. For an involution defining by swapping paths after a first intersection to be weight preserving we need this key property: *if two paths intersect then when they reach this intersection they have both made the same number of steps* This is achieved by making the starting points $(M - i, i)$ for $1 \leq i \leq M$; the weights obtained by the path $P_i$ from $(M - i, i)$ should give $e_{\lambda_i}(x_1, \ldots, x_N)$, so the path must have exactly $N$ steps, of which exactly $\lambda_i$ are right. Therefore $P_i$ ends at $(M - i + \lambda_i, i + N - \lambda_i)$. (Note that if $N < \lambda_1$ then there are no paths at all from $(M - 1, 1)$ to $(M - 1 + \lambda_1, 1 + N - \lambda_1)$; correspondingly $e_{\lambda_1}(x_1, \ldots, x_N) = 0$ and $s_{\lambda_1}(x_1, \ldots, x_N) = 0$.)

Given a non-intersecting tuple of paths $(P_1, \ldots, P_M)$, let $t$ be the $\lambda'$ tabloid with entries in column $i$ recording the step numbers of the right-steps made by $P_i$. Suppose that $t(a, i) > t(a, i + 1)$. Then $P_i$ has made strictly more steps before its $a$th step right than $P_{i+1}$; therefore $P_i$ and $P_{i+1}$ meet on or before step $a$. The converse also holds. Hence non-intersecting paths are in a weight-preserving bijection with semistandard tableaux of shape $\lambda'$.

15. (a), (c) Since $P(x_1, \ldots, x_N)$ is symmetric, it is determined by the coefficient of $x^\lambda$ for each $\lambda \vdash n$ with $\ell(\lambda) \leq N$. Let $\ell(\lambda) = M$. The monomial $x^\lambda$ appears in $(\sum_{i \in I} x_i)^n$ if and only if $I \supseteq \{1, \ldots, M\}$; the coefficient is

$$\binom{n}{\lambda_1, \ldots, \lambda_N}$$
since we must take \( x_i \) from exactly \( \lambda_i \) of the brackets, for each \( i \in \{1, \ldots, M\} \). There are exactly \( \binom{N-M}{k-M} \) \( k \)-subsets of \( \{1, \ldots, N\} \) that contain \( \{1, \ldots, M\} \), hence

\[
P(x_1, \ldots, x_N) = \sum_{\lambda \vdash n, \ell(\lambda) \leq N} \left( \frac{N}{\lambda_1, \ldots, \lambda_N} \right) \left( \sum_{k=M}^{N} (-1)^{n-k} \binom{N-M}{k-M} \right) \text{mon}_\lambda(x_1, \ldots, x_N).
\]

The inner sum vanishes unless \( N = M \). Hence

\[
P(x_1, \ldots, x_N) = (-1)^{n-N} \sum_{\lambda \vdash n, \ell(\lambda) = N} \left( \frac{n}{\lambda_1, \ldots, \lambda_N} \right) \text{mon}_\lambda(x_1, \ldots, x_N).
\]

This answers (c) and shows that if \( n < N \) then \( P(x_1, \ldots, x_N) = 0 \) and if \( n = N \) then

\[
P(x_1, \ldots, x_n) = \left( \frac{n}{1, \ldots, 1} \right) \text{mon}_{(1, \ldots, 1)}(x_1, \ldots, x_N) = N! x_1 \ldots x_N.
\]

(b) Symmetric \( n \)-multilinear maps \( V \times \cdots \times V \to \mathbb{C} \) correspond to elements of \( (\text{Sym}^n V)^\ast \). There is a map \( V^\ast \to (\text{Sym}^n V)^\ast \) defined by \( \theta \mapsto \theta^n \) with dense image. Taking \( f(v_1, \ldots, v_n) = \theta^n(v_1, \ldots, v_n) = \theta(v_1) \ldots \theta(v_n) \) we see that \( g(u, \ldots, u) = \theta(u)^n \). So it is sufficient to prove that if \( \theta \in V^\ast \) then

\[
\theta(v_1) \ldots \theta(v_n) = \frac{1}{n!} \sum_{I \subseteq \{1, \ldots, n\}} (-1)^{n-|I|} \theta(\sum_{i \in I} v_i)^n.
\]

Setting \( \theta(v_i) = x_i \), this is precisely the identity in (a).

Remark: for an alternative proof see [16]. Darij Grinberg has shown me an elegant proof of the strong result that if \( f(x_1, \ldots, x_n) \) is any polynomial then

\[
\sum_{I \subseteq \{1, \ldots, n\}} (-1)^{n-|I|} g(\sum_{i \in I} v_i) = \sum_{\sigma \in \text{Sym}_n} f(v_{1\sigma^{-1}}, \ldots, v_{n\sigma^{-1}})
\]

where \( g(u) = f(u, \ldots, u) \). This immediately implies (b).

16. See [8, §3.2].

17. An equivalent result is stated after Theorem 1.1 in [3]. The key point is that the signs of any two border-strip tableaux of shape \( \lambda \) and content \( (1^{|\gamma|}, \ell^w) \) agree. This can most easily be seen using the abacus: if \( A \) is an \( \ell \)-runner abacus representing \( \lambda \) and \( b \) and \( b' \) are beads on \( A \) then in any sequence of single-step upward bead moves taking \( A \) to an abacus representing \( \gamma \), the parity of the number of times bead \( b \) moves past bead \( b' \) is the same.

18. See [17, §2.3].
19. (a) If \( n \geq \ell m \) then the numbers \( n, n-\ell, \ldots, n-(m-1)\ell \) cover all residue classes modulo \( m \), and so \( n = a\ell + bm \) for some \( a, b \in \mathbb{N}_0 \). Let \( N \) be the largest number not of this form. If \( N + \ell = a\ell + bm \) then \( b = 0 \); similarly \( N + m \) is a multiple of \( \ell \). Hence \( N = \ell m - \ell - m \).

(b) Take an abacus \( A \) representing a simultaneous \( \ell \)-core and \( m \)-core partition with beads in all negative positions and a gap in position 0. If there is a bead in position \( k \) of \( A \) then there are beads in all positions \( k - (a\ell + bm) \) for \( a, b \in \mathbb{N}_0 \). Hence \( k \) is not of the form \( a\ell + bm \), so by (a), \( k \leq \ell m - \ell - m \). Therefore \( A \) has only finitely many beads in positive positions.

(c) See [1]. There are some simplifications in the case \( m = \ell + 1 \), when the number of simultaneous cores is the Catalan number \( \frac{1}{2\ell+1} \binom{2\ell+1}{\ell} \).

20. By two applications of Young’s Rule, \( s_\lambda h_2^2 = \sum \mu c_\mu s_\mu \) where \( [\mu] \) is obtained from \( [\lambda] \) by adding two boxes in any way. If these additions make a hook shape, so the added boxes are either in the same row, or in the same column, then \( c_\mu = 1 \), otherwise \( c_\mu = 2 \). Another application of Young’s Rule to \( s_\lambda h_2 \) now shows that \( s_\lambda p_2 = s_\lambda (2h_2 - h_1^2) = \sum s_\mu sgn(\mu/\lambda) s_\mu \). This proves the Murnaghan–Nakayama rule for addition of 2-hooks.

21. By Question 3(e) we have \( p_r = \sum_{k=0}^{r-1} (-1)^k (r-k) h_{r-k} e_k \). Fix a skew-partition \( \mu/\lambda \) of \( r \) and let \( T \) be the set of all \( \mu/\lambda \)-tableaux such that

(a) No two 1s appear in the same column;
(b) No two 2s appear in the same row;
(c) Exactly one 1 is distinguished.

Given \( t \in T \), define \( sgn(t) = (-1)^k \) where \( k \) is the number of 2s. By the Young and Pieri rules, and the identity above, \( \sum_{t \in T} sgn(t) \) is the coefficient of \( s_\mu \) in \( s_\lambda p_r \). Note that \( T \) is empty unless \( \mu/\lambda \) is a disjoint union of hooks (equivalently, \( [\mu/\lambda] \) contains no \( 2 \times 2 \) box), so we may assume that this is the case.

If \( v/\lambda \) is a hook in \( \mu/\lambda \), define its terminal box to be the box \( (i,j) \in [v/\lambda] \) such that \( (i+1,j) \notin [v/\lambda] \) and \( (i,j-1) \notin [v/\lambda] \). For example, the 7-hook shown in Figure 1 has terminal box in position \( (2,5) \).

We define an involution \( J : T \rightarrow T \) as follows: let \( v/\lambda \) be the highest hook in \( \mu/\lambda \) not containing the distinguished entry 1*, or the hook containing 1* if this is the only hook. If 1* is not in the terminal box of \( v/\lambda \) then flip the entry in this box; this gives a new element of \( T \) with opposite sign. Otherwise leave \( t \) fixed. The involution \( J \) is sign-reversing on its non-fixed-points. Moreover there is a fixed tableau \( t \) if and only if \( \mu/\lambda \) is an \( r \)-hook, and in this case, \( t \) is unique and the number of 2s in
t is \( \text{ht}(\mu/\lambda) \). Hence

\[
\sum_{t \in \mathcal{T}} \text{sgn}(t) = \begin{cases} 
\text{sgn}(\mu/\lambda) & \text{if } \mu/\lambda \text{ is a hook} \\
0 & \text{otherwise.}
\end{cases}
\]

as required.

Example: if \( \lambda = (1) \) and \( \nu = (3,2) \) then \(|\mathcal{T}| = 5\); the unique fixed point and the two pairs swapped by \( J \) are shown below:

\[
\begin{array}{ccc}
1^{*} & 2 \\
1 & 2
\end{array},
\begin{array}{ccc}
1^{*} & 1 \\
1 & 2
\end{array} \leftrightarrow \begin{array}{ccc}
1^{*} & 2 \\
1 & 2
\end{array},
\begin{array}{ccc}
1^{*} & 2 \\
1 & 1
\end{array} \leftrightarrow \begin{array}{ccc}
1^{*} & 2 \\
1 & 2
\end{array}.
\]

If \( \lambda = (2,1) \) and \( \nu = (3,2,2) \) then \( J \) has no fixed points, \(|\mathcal{T}| = 8\) and \( J \) is defined by

\[
\begin{array}{ccc}
1^{*} & 2 \\
1 & 2
\end{array} \leftrightarrow \begin{array}{ccc}
1 & 2 \\
1 & 2
\end{array},
\begin{array}{ccc}
1^{*} & 2 \\
1 & 2
\end{array} \leftrightarrow \begin{array}{ccc}
1^{*} & 2 \\
1 & 2
\end{array},
\begin{array}{ccc}
1^{*} & 1 \\
1 & 2
\end{array} \leftrightarrow \begin{array}{ccc}
1^{*} & 1 \\
1 & 2
\end{array}.
\]

Reference: I am grateful to Darij Grinberg for observing that a similar argument is used to prove Theorem 6.3 in [11].

22. By definition \( \beta = \lambda \cdot \sigma \). By (4.2) we have

\[
(\lambda \cdot \sigma)_i = \lambda_{i\sigma^{-1}} + i - i\sigma^{-1}.
\]

Hence if \( j\sigma > (j + 1)\sigma \) then \( (\lambda \cdot \sigma)_{j\sigma} = \lambda_j + j\sigma - j > \lambda_{j+1} + (j + 1)\sigma - (j + 1) = (\lambda \cdot \sigma)_{(j+1)\sigma} \), so \( \beta_{j\sigma} > \beta_{(j+1)\sigma} \), proving (a). Since \( j\sigma > (j + 1)\sigma \), \( \beta \) is not a partition. Therefore if \( \lambda \cdot \sigma \) is a partition then \( \sigma \) has no inversions, and so \( \sigma = \text{id}_{\text{Sym}_N} \), proving (b). Hence the stabiliser under the dot action of \( \lambda \) is trivial, so the orbit has size \( N! \), proving (c).

23. (a) Note that \( S(m,n) \setminus S(m+1,n) \), respectively \( S(m,n-1) \setminus S(m+1,n-1) \), is the set of \(+/-\) words with exactly \( m \) good \(-\) entries out of \( n \), respectively \( n - 1 \).

Pair up \(+\) and \(-\) in the expected way, so in the example word \(+ - + - - - - \) the unpaired \(-\) entries are in red. The analogue of the \( F_1 \) coplactic map is defined by replacing the rightmost unpaired \(-\) with (an unpaired) \(+\). This does not change the number of good \(-\) entries; by Lemma 4.4 it gives a bijection between the two sets.

(b) Repeatedly apply the bijection in (a) until all \(-\) entries are good. The resulting word is in \( S(m,m) \). Note that since each \(-\) left of the rightmost unpaired \(-\) has the same paired/unpaired status after applying \( F_1 \), the map is simply: \textit{change all unpaired \(-\) entries to \(+\).}
25. (a) The equivalent identity for Young’s Rule for symmetric polynomials, with $a_{\lambda+\delta}/a_\delta$ replacing $s_\lambda$, was proved in Corollary 3.9; now apply Theorem 4.10. The required form of Pieri’s Rule can be proved similarly.

(b) Outline: suppose that $\omega(s_\lambda) = \sum_\nu A_{\nu\lambda}s_\lambda$. Show that $AK = \tilde{K}$ where $K_{\lambda\mu} = |SSYT(\lambda, \mu)|$ and $\tilde{K}_{\lambda\mu} = |SSYT(\lambda', \mu)|$. Now use that $K$ is unitriangular, and so invertible, to determine $A$.

26. We have

$$h_{\mu_1} \ldots h_{\mu_k} = \prod_{i=1}^k \sum_{\beta(i) = \mu_i} \frac{p_{\beta(i)}}{z_{\beta(i)}} = \prod_{i=1}^k \sum_{\beta(i) = \mu_i} p_{\beta(i)} \prod_{j=1}^n \frac{1}{j! B_{ij}}!$$

where $B_{ij}$ is the number of parts of $\beta(i)$ equal to $j$ for each $j \in \{1, \ldots, n\}$. Suppose that $\alpha \vdash n$ has exactly $a_j$ parts equal to $j$ for each $j \in \{1, \ldots, n\}$. We get a contribution to the coefficient of $p_\alpha$ from every $k$-tuple of partitions $\alpha(1), \ldots, \alpha(k)$ such that $\sum_i B_{ij} = a_j$ for each $j \in \{1, \ldots, n\}$ and $\sum_j jB_{ij} = |\alpha(i)| = \mu_i$. Thus the $k \times n$ matrix $B$ is an $\alpha$-packing matrix, and the coefficient of $p_\alpha$ is

$$\sum_{B} \prod_{i=1}^k \prod_{j=1}^n \frac{1}{j! B_{ij}}! = \sum_{B} \prod_{j=1}^n \left( \frac{a_j}{a_j! j!^{a_j}} \right) = \frac{1}{z_\alpha} \sum_{B} \prod_{j=1}^n \left( \frac{a_j}{b_1 \ldots b_k} \right) = \frac{1}{z_\alpha} \pi''(\alpha)$$
where the final equality uses Claim 1 in the proof of Theorem 5.3.

27. For (a) see [14, 7.10.2]: the proof given above of Proposition 1.16 generalizes routinely. The identity \( s_{\lambda} h_{\alpha} = \sum_{\lambda' \vdash n} K_{\lambda'/\nu,\lambda} s_{\lambda} \) can be proved by repeated applications of Young’s Rule, as in Corollary 3.9 (which it generalizes). By (a), \( s_{\lambda}/\nu \) is a symmetric function, so

\[
s_{\lambda}/\nu = \sum_{\alpha \vdash n} K_{\lambda'/\nu,\alpha} \mon_{\alpha}.
\]

Using the orthogonality of the monomial and complete homogeneous symmetric functions (see Theorem 5.2) we get

\[
\langle s_{\lambda}/\nu, h_{\alpha} \rangle = K_{\lambda'/\nu,\lambda} = \langle s_{\nu} h_{\alpha}, s_{\lambda} \rangle.
\]

This proves (c). Since the \( h_{\alpha} \) for \( \alpha \) form a basis of \( \Lambda \), this implies that \( \langle s_{\lambda}/\nu, f \rangle = \langle s_{\nu} f, s_{\lambda} \rangle \) for all \( f \in \Lambda \), proving (d).

28. Border-strip tableaux of shape a skew-partition are defined in [14, p346]. Let \( c_{\lambda}/\nu(\alpha) = \sum T \sgn(T) \) where the sum is over all border-strip skew-tableaux of shape \( \lambda/\nu \) and type \( \alpha \). Generalizing Corollary 3.13 in the same way as Young’s Rule was generalized in Question 26(b), we get

\[
s_{\nu} p_{\alpha} = \sum_{\lambda' \vdash n} c^{\lambda'/\nu}(\alpha) s_{\lambda}.
\]

29. See [14, Theorem 7.16.2]. Outline. Theorem 2.1 is the special case \( \nu = \emptyset \). The path model used in the proof generalizes as follows: take starting points \((\nu_i + M - i, 1)\) and final destinations \((\lambda_i + M - i, N)\) for \( i \in \{1, \ldots, M\} \). The sum of the weights of non-intersecting paths is \( s_{\lambda}/\nu(x_1, \ldots, x_N) \). Suppose that the final destination of the path starting at \((\mu_i + M - i, 1)\) is \((\lambda_i \tau + M - i \tau, N)\) for each \( i \). By (4.2), these paths are counted in the summand \( \prod_{i=1}^{N} h_{\lambda_i \tau - \mu_i \tau + i} = h_{\lambda \tau - 1 - \mu} \) of the right-hand side of

\[
s_{\lambda}/\nu = \sum_{\sigma \in \Sym_M} h_{\lambda \cdot \sigma - \nu} \sgn(\sigma).
\]

If we swap the paths starting at \((\mu_i + M - i, 1)\) and \((\mu_j + M - j, 1)\) after their first intersection, they now end at \((\lambda_j \tau + M - j \tau, N)\) and \((\lambda_i \tau + M - i \tau, N)\), so as expected, the new permutation is \((i,j) \tau \).

30. See [12, §2] for the definition of the \( J \) involution on skew-tableaux: Proposition 4 is the generalization of Lemma 4.4. The generalization of Lemma 4.7 is as follows: let \( \alpha/\beta \) be a skew-partition and let \( \mu \) be a partition with \( \ell(\mu) \leq N \). Then \( J \) is an involution on

\[
\bigcup_{\sigma \in \Sym_N} \SSYT(\alpha/\beta, \mu \cdot \sigma)
\]
with fixed points precisely the latticed tableaux in \(SSYT(\alpha/\beta, \mu)\) and such that if \(t \in SSYT(\alpha/\beta, \mu \cdot \sigma)\) is \(k\)-unlatticed, with \(k\) minimal, then \(J(t) \in SSYT(\alpha/\beta, \mu \cdot (\sigma(k, k+1)))\).

31. Each part is a routine application of results already proved.

32. (a) Observe that when we specialize by \(x_1, \ldots, x_c \to 1,\) and \(x_{c+1}, \ldots \to 0,\) the monomial symmetric function \(\text{mon}_\lambda\) sent to 0 if \(\ell(\lambda) > c\) and otherwise to the number of words in \(W_n\) with entries from \(\{1, \ldots, c\}\) whose content is a rearrangement of \(\lambda.\) By Pólya’s Theorem, the coefficient of \(\text{mon}_\lambda\) in \(\text{cyc}_G\) is the number of orbits of \(G\) on words of content \(\lambda.\) Therefore specializing in this way counts the number of words in \(W_n\) whose content is a rearrangement of \(\lambda,\) up to the action of \(G.\) (See (b) for an example.) Since \(p_\lambda\) specializes to \(c^{\ell(A)}\), Pólya Theorem implies that the number of orbits of \(G\) on words in \(W_n\) with entries from \(\{1, \ldots, c\}\), is

\[
\frac{1}{|G|} \sum_{g \in G} c^{\ell(\text{cyctype}(g))}
\]

as required.

(b) This is a routine application of (a). To illustrate the specialization above, if \(c = 3\) then \(3\text{mon}_{(2,2)} = 3(x_1x_2 + x_2x_3 + x_1x_3 + \cdots),\) seen in \(\text{cyc}_G\) in Example 5.11(3) corresponds to 3 orbits on words with content \((2,2,0),\) and so to 9 orbits of words whose content is a rearrangement of \((2,2,0).\)

Acknowledgements

I thank Darij Grinberg for many exceptionally helpful comments, corrections, and suggestions for improvements to the exposition. I also thank Eoghan McDowell for helpful comments and corrections. Of course I have full responsibility for all the remaining errors.
